ABSTRACT

Background

Foot ulcers are a major complication of diabetes mellitus, often leading to amputation. Growth factors derived from blood platelets, endothelium, or macrophages could potentially be an important treatment for these wounds but they may also confer risks.

Objectives

To assess the benefits and harms of growth factors for foot ulcers in patients with type 1 or type 2 diabetes mellitus.

Search methods

In March 2015 we searched the Cochrane Wounds Group Specialised Register, The Cochrane Central Register of Controlled Trials (CENTRAL) (The Cochrane Library), Ovid MEDLINE, Ovid MEDLINE (In-Process & Other Non-Indexed Citations, Ovid EMBASE and EBSCO CINAHL. There were no restrictions with respect to language, date of publication or study setting.

Selection criteria

Randomised clinical trials in any setting, recruiting people with type 1 or type 2 diabetes mellitus diagnosed with a foot ulcer. Trials were eligible for inclusion if they compared a growth factor plus standard care (e.g., antibiotic therapy, debridement, wound dressings) versus placebo or no growth factor plus standard care, or compared different growth factors against each other. We considered lower limb amputation (minimum of one toe), complete healing of the foot ulcer, and time to complete healing of the diabetic foot ulcer as the primary outcomes.

Data collection and analysis

Independently, we selected randomised clinical trials, assessed risk of bias, and extracted data in duplicate. We estimated risk ratios (RR) for dichotomous outcomes. We measured statistical heterogeneity using the I² statistic. We subjected our analyses to both fixed-effect and random-effects model analyses.
Main results

We identified 28 randomised clinical trials involving 2365 participants. The cause of foot ulcer (neurologic, vascular, or combined) was poorly defined in all trials. The trials were conducted in ten countries. The trials assessed 11 growth factors in 30 comparisons: platelet-derived wound healing formula, autologous growth factor, allogeneic platelet-derived growth factor, transforming growth factor β2, arginine-glycine-aspartic acid peptide matrix, recombinant human platelet-derived growth factor (becaplermin), recombinant human epidermal growth factor, recombinant human basic fibroblast growth factor, recombinant human vascular endothelial growth factor, recombinant human lactoferrin, and recombinant human acidic fibroblast growth factor. Topical intervention was the most frequent route of administration. All the trials were underpowered and had a high risk of bias. Pharmaceutical industry sponsored 50% of the trials.

Any growth factor compared with placebo or no growth factor increased the number of participants with complete wound healing (345/657 (52.51%) versus 167/482 (34.64%); RR 1.51, 95% CI 1.31 to 1.73; I² = 51%, 12 trials; low quality evidence). The result is mainly based on platelet-derived wound healing formula (36/56 (64.28%) versus 7/27 (25.92%); RR 2.45, 95% CI 1.27 to 4.74; I² = 0%, two trials), and recombinant human platelet-derived growth factor (becaplermin) (205/428 (47.89%) versus 109/335 (32.53%); RR 1.47, 95% CI 1.23 to 1.76, I² = 74%, five trials).

In terms of lower limb amputation (minimum of one toe), there was no clear evidence of a difference between any growth factor and placebo or no growth factor (19/150 (12.66%) versus 12/69 (17.39%); RR 0.74, 95% CI 0.39 to 1.39; I² = 0%, two trials; very low quality evidence). One trial involving 55 participants showed no clear evidence of a difference between recombinant human vascular endothelial growth factor and placebo in terms of ulcer-free days following treatment for diabetic foot ulcers (RR 0.64, 95% CI 0.14 to 2.94; P value 0.56, low quality of evidence).

Although 11 trials reported time to complete healing of the foot ulcers in people with diabetes, meta-analysis was not possible for this outcome due to the unique comparisons within each trial, failure to report data, and high number of withdrawals. Data on quality of life were not reported. Growth factors showed an increasing risk of overall adverse event rate compared with compared with placebo or no growth factor (255/498 (51.20%) versus 169/332 (50.90%); RR 0.83; 95% CI 0.72 to 0.96; I² = 48%; eight trials; low quality evidence). Overall, safety data were poorly reported and adverse events may have been underestimated.

Authors’ conclusions

This Cochrane systematic review analysed a heterogeneous group of trials that assessed 11 different growth factors for diabetic foot ulcers. We found evidence suggesting that growth factors may increase the likelihood that people will have complete healing of foot ulcers in people with diabetes. However, this conclusion is based on randomised clinical trials with high risk of systematic errors (bias). Assessment of the quality of the available evidence (GRADE) showed that further trials investigating the effect of growth factors are needed before firm conclusions can be drawn. The safety profiles of the growth factors are unclear. Future trials should be conducted according to SPIRIT statement and reported according to the CONSORT statement by independent investigators and using the Foundation of Patient-Centered Outcomes Research recommendations.

Plain Language Summary

Growth factors for treating diabetic foot ulcers

What are diabetic foot ulcers?

People who suffer from diabetes mellitus (usually referred to as ‘diabetes’) can develop wounds (ulcers) on their feet and ankles. These diabetic foot ulcers can take a long time to heal, and affect quality of life for people with diabetes. In some people, failure of these ulcers to heal can contribute to the need for some level of amputation on the foot. Any treatments that encourage diabetic foot ulcers to heal will be valuable.

What are growth factors?

Growth factors are substances that occur naturally in the body. They promote growth of new cells and healing of wounds. Treatment of diabetic foot ulcers with growth factors may improve the healing of ulcers.
This Cochrane review tried to identify the benefits and harms of treating diabetic foot ulcers with growth factors in addition to providing standard care (i.e. pressure relief, removal of dead tissue from the wound, infection control and application of dressings).

Findings of this review

The review authors searched the medical literature up to 3 March 2015, and identified 28 relevant medical trials, with a total of 2365 participants. The trials were performed in ten different countries, generally in out-patient settings. All the trials had low numbers of participants, which makes potential overestimation of benefits and underestimation of harms more likely. Half of the trials were sponsored by the pharmaceutical industry that produces these growth factors.

The trials tested 11 different types of growth factor, usually by applying them to the ulcer surface. Growth factors had no effect on the risk of having one toe or more amputated when compared with either another growth factor, or placebo (inactive fake medicine), or standard care alone (evidence from four trials). However, when compared with placebo or no growth factor, growth factors seemed to make complete healing of ulcers (wound closure) more likely to occur (evidence from 12 trials).

Shortcomings of the trials included in this review

None of the trials reported data on participants’ quality of life. Harms caused by treatments were poorly reported, so the safety profile of growth factors remains unclear.

It is clear that more trials are required to assess the benefits and harms of growth factors in the treatment of diabetic foot ulcers. These trials should be well-designed, conducted by independent researchers (not industry-sponsored), and have large numbers of participants. They should report outcomes that are of interest to patients, such as: how many of the participants’ ulcers healed, and how long the healing took; any level of amputation in the foot; quality of life; ulcer-free days following treatment; and harms caused by treatment, including whether there are any potential cancer risks.
# SUMMARY OF FINDINGS FOR THE MAIN COMPARISON

Any growth factor compared with placebo or no growth factor for diabetic foot ulcer

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

**CI:** Confidence interval; **RR:** Risk ratio; **HR:** Hazard ratio;

**GRADE Working Group grades of evidence**

**High quality:** Further research is very unlikely to change our confidence in the estimate of effect.

**Moderate quality:** Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

**Low quality:** Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

**Very low quality:** We are very uncertain about the estimate.

---

1 Assumed risk is based on the risks for the control group in the meta-analysis.

2 Downgraded one level for limitations in design and execution: Eleven out thirteen trials assessing this outcome have high risk for selection bias. And outcome assessment was performed in unclear fashion.

3 Downgraded one level for inconsistency ($I^2$: 51%).

4 Downgraded one level for limitations in design and execution.

5 Downgraded two levels for imprecision: small sample size and very low rate of events conducting to wide confidence intervals.

6 Downgraded one level for imprecision: Low rate of adverse events resulting in wide confidence intervals.
BACKGROUND

See Appendix 1 for medical and epidemiological terms.

Description of the condition

It is estimated that in 2011, approximately 366 million people had diabetes, that is 7.0% of the world’s population (Bakker 2012a). Around 80% of these people live in low- or middle-income countries. By 2030, the global estimate is expected to rise to 552 million - that is 8.3% of the adult population (Bakker 2012a). The development of foot ulcers is a major complication of diabetes mellitus (Boulton 2005; Lipsky 2004; Rathur 2007; Richard 2008; Sibbald 2008). The International Working Group on the Diabetic Foot defines a foot ulcer as a full thickness wound involving the foot or ankle (Lavery 2008), that is, “a wound penetrating through the dermis” (Schaper 2004). A wound is a break in the epithelial integrity of the skin and may be accompanied by disruption of the structure and function of underlying normal tissue (Enoch 2008).

Epidemiology of the foot ulcer in people with diabetes

The proportion of diabetic foot ulcers among people with diabetes mellitus varies across studies, ranging from 5% to 43% (Appendix 2). There are four classification systems for diabetic foot ulcers that are summarised in Appendix 3 (Ince 2008; Lavery 1996; Schaper 2004; Wagner 1981). Outcomes for diabetic foot ulcers are predicted by ulcer area, presence of peripheral arterial disease, duration of diabetes, and presence of osteomyelitis (infection of bone) (Ince 2007; Lavery 2009; Oyibo 2001).

There is a close relationship between the presence of a diabetic foot ulcer and the amputation of a toe or a lower limb (Boulton 2008; Bakker 2012b; Yones 2004). Indeed, Boulton 2008 and Bakker 2012a reported that more than 85% of such amputations were preceded by an active foot ulcer. Amputation is a major complication for people with a diabetic foot ulcer (Bartus 2004; Schaper 2012a), and is a risk factor for increased mortality (Izumi 2009). The incidence of amputations is higher in people with diabetes (range 0.64 to 5.25 per 1000 person-years) than in people without diabetes (0.03 to 0.24 per 1000 person-years) (Schaper 2012a). The reported annual incidence of major amputation in industrialised countries ranges from 0.06 to 3.83 per 1000 diabetic people (Jeffcoate 2005). The incidence varies between countries, races, and communities (Jeffcoate 2005), however, there is concern about the methods used to calculate incidence and prevalence of amputation in people with diabetes (Van Houtum 2008). The incidence of reamputation in diabetic people with history of amputation within two years is almost 50% (Kanade 2007). Reamputation could be due to poor selection of the original amputation level through efforts to save as much of the lower extremity as possible (Skoutas 2009).

Diabetic foot ulcer pathways

The commonest causes of foot ulcers in people with diabetes are peripheral neuropathy (nerve damage), foot deformity, external trauma, peripheral vascular disease, and peripheral oedema (Boulton 2008; Figueroa-Romero 2008; Quattrini 2008; Schaper 2012b; Szabo 2009). Other significant risk factors include being over 75 years of age, use of insulin, poor psychosocial status, hyperkeratosis (thickening of the outermost layer of skin), macrovascular and microvascular complications, and duration of diabetes (Chao 2009; Iversen 2008; Leymarie 2005).

Description of the intervention

Many studies have experimented with biological agents, aiming to modify the pathophysiology of diabetic foot ulcers. Growth factors are examples of these biological agents, and are considered to be a potentially important technological advance in the area of wound healing (Papanas 2007).

How the intervention might work

Normal wound healing has four phases: coagulation, inflammation, migration/proliferation, and remodelling (Papanas 2008). Sheehan 2006 observed that a 53% or greater reduction in the area of a foot ulcer area after four weeks of observation was a robust predictor of healing at 12 weeks. Since chronic wound healing may be limited by a lack of the necessary growth factors, healing may be speeded up by replacing or stimulating these growth factors, so enhancing the formation of granulation tissue, that precedes healing, within the wounds (Amery 2005; Barrientos 2008; Bennett 2003; Galkowska 2006; Grazul-Bilska 2003; Köveker 2000; Pradhan 2009; Viswanathan 2006). See Appendix 4 for wound-healing and tissue-forming ability of growth factors.
Why it is important to do this review

Diabetic foot ulcers represent a pervasive and important problem for people suffering from diabetes mellitus. Foot-related problems are responsible for up to 50% of diabetes-related hospital admissions (Albert 2002; Boulton 2001; Boulton 2005). Foot ulcers cause a low quality of life and often lead to lower extremity amputation (Armstrong 2008; Boutouille 2008; Goodridge 2006; Herber 2007; Kinmond 2003; Meatherall 2005; Price 2004; Ribu 2008; Schaper 2012a; Valensi 2007). Amputation causes prolonged hospitalisation, rehabilitation, and an increased need for home care and social services (Ali 2008; Ashry 1998; Girod 2003; Habib 2010; Lantis 2009; Redekop 2004; Siriwardana 2007; Van Acker 2000; Viswanathan 2005; Willrich 2005). Management of the diabetic foot has major economic consequences for patients, their families and society (Jeffcoate 2003; Jeffcoate 2004; Milman 2001; Rathur 2007; Smith 2004), and quality of life for caregivers is also unsatisfactory (Nabuurs-Frassen 2005).

Several randomised clinical trials (RCTs) have assessed the benefits and harms of growth factors for treating diabetic foot ulcers, and they need a critical appraisal for risk of systematic errors that can cause bias (that is, could cause overestimation of benefits and underestimation of harms) and risk of random errors (that is, play of chance). Several narrative reviews and meta-analyses have assessed the use of growth factors for treating diabetic foot ulcers, but these have been prone to errors (that is, lack of rigorous assessment of bias risks; no or insufficient evaluation of the risks of random errors; no evaluation of statistical heterogeneity; poor reporting of search methods; and potential conflicts of interest as authors of the reviews were also trialists of the included trials) (Hinchliffe 2008; Papanas 2008).

A systematic review of the most up to date evidence, including a rigorous assessment of the quality of that evidence, may help clinicians and clinical researchers make informed decisions about the use of growth factors for treating diabetic foot ulcers.

OBJECTIVES

To assess the benefits and harms of growth factors for diabetic foot ulcers in patients with type 1 or type 2 diabetes mellitus.

METHODS

Criteria for considering studies for this review

Types of studies
Randomised controlled trials (RCTs) in any setting.

Types of participants
Adults (>18 years of age) with a diabetic foot ulcer of any aetiology.

Types of interventions
See Appendix 1.

Experimental interventions
1. Platelet-derived wound healing formula
2. Autologous growth factor
3. Allogeneic platelet-derived growth factor
4. Transforming growth factor β2
5. Arginine-glycine-aspartic acid (RGD) peptide matrix
6. Recombinant human platelet-derived growth factor (becaplermin)
7. Recombinant human epidermal growth factor
8. Recombinant human basic fibroblast growth factor
9. Recombinant human vascular endothelial growth factor (telbermin)
10. Recombinant human lactoferrin
11. Recombinant human acidic fibroblast growth factor

In addition to receiving the experimental intervention (growth factors) participants also received standard care (see below).

Control interventions
1. Standard care (for example, antibiotic therapy, debridement, wound dressings) alone or plus placebo. We noted whether the standard care was delivered similarly to intervention groups and noted any differences between intervention groups.

Types of outcome measures

Primary outcomes
1. Complete wound healing (defined as 100% epithelialisation or skin closure without drainage).
2. Lower limb amputation (minimum of one toe).
3. Time to complete healing of the diabetic foot ulcer.

Secondary outcomes
1. Ulcer-free days following treatment for diabetic foot ulcers (free from any recurrence).
2. Quality of life (as measured by a validated scale).
3. Adverse events: number and type of adverse events defined as any untoward medical occurrence - not necessarily having a causal relationship with the treatment. We reported separately on adverse events that led, and did not lead, to treatment...
discontinuation. We defined serious adverse events according to the International Conference on Harmonisation (ICH) Guidelines as any event that at any dose results in death, is life-threatening, requires in-patient hospitalisation or prolongation of existing hospitalisation, results in persistent or significant disability, or is a congenital anomaly/birth defect, and any important medical event that may have jeopardised the patient or requires intervention to prevent it (ICH-GCP 1997). All other adverse events were considered non-serious.

Search methods for identification of studies

Electronic searches

The following electronic databases were searched to identify reports of relevant randomised clinical trials:

1. The Cochrane Wounds Group Specialised Register (searched 03 March 2015);
2. The Cochrane Central Register of Controlled Trials (CENTRAL) (The Cochrane Library 2015, Issue 2);
3. Ovid MEDLINE (1946 to March 2, 2015);
4. Ovid MEDLINE (In-Process & Other Non-Indexed Citations) (March 2, 2015);
5. Ovid EMBASE (1974 to March 2, 2015);

We used the following search strategy in The Cochrane Central Register of Controlled Trials (CENTRAL):

1. MeSH descriptor Foot Ulcer explode all trees
2. MeSH descriptor Diabetic Foot explode all trees
3. diabet* NEAR/3 ulcer*:ti,ab,kw
4. diabet* NEAR/3 (foot or feet):ti,ab,kw
5. diabet* NEAR/3 wound*:ti,ab,kw
6. (#1 OR #2 OR #3 OR #4 OR #5)
7. MeSH descriptor Intercellular Signaling Peptides and Proteins explode all trees
8. MeSH descriptor Insulin-Like Growth Factor Binding Proteins explode all trees
9. growth NEXT factor*:ti,ab,kw
10. EGF or FGF or PDGF:ti,ab,kw
11. plermin or regranex or becaplermin:ti,ab,kw
12. (#7 OR #8 OR #9 OR #10 OR #11)
13. (#6 AND #12)

This strategy was adapted to search Ovid MEDLINE, Ovid EMBASE and EBSCO CINAHL (please see Appendix 5). The MEDLINE search was combined with the Cochrane Highly Sensitive Search Strategy for identifying randomised trials in MEDLINE: sensitivity- and precision-maximizing version (2008 revision) (Lefebvre 2011). The EMBASE and CINAHL searches were combined with the trial filters developed by the Scottish Intercollegiate Guidelines Network (SIGN) (SIGN 2010). There were no restrictions with respect to language, date of publication or study setting.

Searching other resources

The following web sites were also searched:

1. Food and Drug Administration (http://www.fda.gov/);
2. European Medicines Agency (http://www.emea.europa.eu);
4. MedWatch The FDA Safety Information and Adverse Event Reporting Program (http://www.fda.gov/Safety/MedWatch/default.htm);
5. Medicines and Healthcare products Regulatory Agency (http://www.mhra.gov.uk/index.htm);
6. Scirus (www.scirus.com);
7. CenterWatch (http://www.centerwatch.com);
8. Evidence in Health and Social Care (http://www.evidence.nhs.uk/);
10. WHO International Clinical Trials Registry Platform Search Portal (http://apps.who.int/trialsearch/).

We also checked the reference lists of all the potentially relevant trials identified by the above methods.

Data collection and analysis

We summarised data using standard Cochrane Collaboration methodologies (Higgins 2011).

Selection of studies

Two review authors (AJM-C, SN) independently assessed each reference identified by the search against the inclusion criteria. We resolved disagreements that arose through discussion. Those references that appeared to meet the inclusion criteria were retrieved in full for further independent assessment by two review authors.

Data extraction and management

One review author independently extracted data (SN) from the included trials using a spreadsheet data extraction form and two review authors (AJM-C, DSR) checked the data entered. We extracted the following data: eligibility criteria, demographics (age, sex, country), characteristic of the ulcers (anatomic site, size, number of ulcers, presence of infection, duration of ulceration), type of diabetes mellitus, duration of diabetes mellitus, ulcer treatments, and outcomes assessed. We discussed any discrepancies between review authors in order to achieve a final consensus.
Assessment of risk of bias in included studies
Independent, three review authors (AJM-C, SN, DSR) assessed the risk of bias of each included trial using the domain-based evaluation as described in the *Cochrane Handbook for Systematic Reviews of Interventions* 5.1.0 (Higgins 2011). See, Appendix 6 for details. Three review authors (LR, PO, JCT) checked these assessments. The review authors discussed discrepancies and achieved consensus.

Overall risk of bias
We made explicit judgements about whether the RCTs were at high risk of bias, according to the criteria given in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011). We assessed the risk of bias as being high if any of the above domains was assessed as being at unclear or high risk of bias. Trials that had adequate generation of allocation sequence, allocation concealment, blinding, handling of incomplete outcome data, and no selective outcome reporting, and that were without other risks of bias were considered to be trials with a low risk of bias. We explored the impact of the risk of bias through undertaking subgroup analyses.

Measures of treatment effect
For binary outcomes, such as incidence of complete wound healing, amputation, and adverse events, we calculated the risk ratio (RR) with 95% confidence intervals (CI) for each. For ulcer-free days following treatment, a time-to-event outcome, we calculated the hazard ratio (HR) with 95% CI (Zavala 2007).

Dealing with missing data
We assessed the percentage of dropouts for each included trial, and for each intervention group, and evaluated whether an intention-to-treat (ITT) analysis had been performed or could have been performed from the available published information. We contacted authors to resolve some queries on this issue. In order to undertake an ITT analysis, we sought data from the trial authors on the number of participants in treatment groups, irrespective of compliance and whether or not participants were later thought to be ineligible, or otherwise excluded from treatment or lost to follow-up. If this information was not forthcoming, we undertook a complete patient analysis, knowing that it might be biased. We included patients with incomplete or missing data in sensitivity analyses by imputing them according to the following scenarios (Hollis 1999).

- Extreme case analysis favouring the experimental intervention (‘best-worse’ case scenario): none of the drop-outs/participants lost from the experimental arm, but all of the drop-outs/participants lost from the control arm experienced the outcome, including all randomised participants in the denominator.
- Extreme case analysis favouring the control (‘worst-best’ case scenario): all drop-outs/participants lost from the experimental arm, but none from the control arm experienced the outcome, including all randomised participants in the denominator.

Assessment of heterogeneity
We quantified statistical heterogeneity using the I² statistic, which describes the percentage of total variation across trials that is due to heterogeneity rather than sampling error (Higgins 2003). We considered statistical heterogeneity to be present if I² was greater than 50% (Higgins 2011). When significant heterogeneity was detected (i.e. when I² exceeded 50%), we attempted to identify the possible causes of heterogeneity.

Assessment of reporting biases
We assessed publication bias and other bias by a funnel-plot (Sterne 2011). We calculated Egger’s test with Comprehensive Meta-analysis software (CMA 2011).

Data synthesis
We calculated pooled estimates and 95% confidence intervals (CI) using fixed-effect model.

Subgroup analysis and investigation of heterogeneity
We had anticipated clinical heterogeneity in the effect of the intervention and we planned to conduct the following subgroup analyses had the data had been available. Furthermore, subgroup analysis would be performed only for complete wound healing (primary outcome).

We could not perform preplanned analyses for clinical subgroups (insulin-using compared to non insulin-using participants, severity and depth of wound, and use or not of antibiotics (Appendix 7; Appendix 8)) due to a lack of available data.

We conducted the following preplanned subgroup analyses.
1. Duration of follow-up: trials with less 20 weeks of follow-up compared to trials with 20 weeks or more of follow-up.
2. Type of growth factor.

The subgroup analyses were only performed for the outcome of complete wound closure.

Sensitivity analysis
We performed the following sensitivity analysis in order to explore the influence of these factors on the intervention effect size.
1. Repeating the analysis taking attrition bias into consideration: ‘Best-worst case’ scenario versus ‘Worst-best case’ scenario

'Summary of findings' tables

We used the principles of the GRADE system to assess the quality of the body of evidence associated with specific outcomes where possible (complete wound closure, lower limb amputation, ulcer-free day following treatment for diabetic foot ulcers, time to complete healing of the diabetic foot ulcer, quality of life, and adverse events) (Guyatt 2011f). We constructed ‘Summary of findings’ tables using the GRADE software. The GRADE approach appraises the quality of a body of evidence on the basis of the extent to which one can be confident that an estimate of effect or association reflects the item being assessed. The quality of a body of evidence considers within-study risk of bias (methodologic quality), the directness of the evidence, heterogeneity of the data, precision of effect estimates, and risk of publication bias (Balshem 2011; Guyatt 2011a; Guyatt 2011b; Guyatt 2011c; Guyatt 2011d; Guyatt 2011e; Guyatt 2011f; Guyatt 2011g; Guyatt 2011h; Guyatt 2011i; Guyatt 2012).

Results of the search

Figure 1. Study flow diagram.

- 385 records identified through database searching.
- 8 additional records identified through other sources.

393 records

393 records screened

351 records excluded

44 full-text articles assessed for eligibility

9 full-text articles excluded due to: case report, non-randomised clinical trial, case series, phase IV (post-marketing surveillance study).

35 references (28 included trials) in qualitative synthesis.

16 included trials in quantitative synthesis (meta-analysis).
Included studies

Tables of Characteristics of included studies show a detailed description of the studies.

Growth factors and populations assessed in the trials

The 28 RCTs reported 11 different growth factors compared with several different control interventions. The experimental interventions included both non-recombinant and recombinant growth factors. The non-recombinant growth factors investigated were: platelet-derived wound healing formula (Holloway 1993; Steed 1992); autologous growth factors (Driver 2006; Kakagia 2007; Saldalamacchia 2004); allogeneic platelet-derived growth factor (Steed 1996); transforming growth factor β2 (Robson 2002); arginine-glycine-aspartic acid (RGD) peptide matrix (Steed 1995b). The recombinant growth factors were recombinant human platelet-derived growth factor (Agrawal 2009; Bhansali 2009; d’Hemecourt 1998; Hardikar 2005; Jaiswal 2010; Landsman 2010; Niezgoda 2005; Steed 1995a; Wieman 1998a); recombinant human epidermal growth factors (Afshari 2005; Chen 2004; Fernández-Montequin 2007; Fernández-Montequin 2009; Tsang 2003; Viswanathan 2006); recombinant human basic fibroblast growth factors (Richard 1995; Tan 2008; Uchi 2009); recombinant human vascular endothelial growth factor (Hanft 2008); recombinant human lactoferrin (Lyons 2007); and recombinant human acidic fibroblast growth factor (Tan 2008).

Twenty trials compared growth factors against no growth factor or against placebo (without or with co-interventions). The comparisons were: no growth factor (d’Hemecourt 1998; Fernández-Montequin 2009; Jaiswal 2010; Saldalamacchia 2004); saline solution (Bhansali 2009; Driver 2006; Holloway 1993; Richard 1995; Steed 1992; Steed 1995b; Steed 1996); or placebo (Agrawal 2009; Hanft 2008; Hardikar 2005; Lyons 2007; Robson 2002; Steed 1995a; Uchi 2009; Viswanathan 2006; Wieman 1998a). The characteristics of the placebo were not sufficiently described in Agrawal 2009, Hardikar 2005, Steed 1995a, Uchi 2009, or Wieman 1998a. Accordingly, only four trials used an appropriate placebo (Hanft 2008; Lyons 2007; Robson 2002; Viswanathan 2006).

Two trials compared one growth factor versus another growth factor, or different doses of the same growth factor (with or without co-interventions). Tan 2008 compared recombinant human acidic fibroblast growth factor versus recombinant human basic fibroblast growth factor. Fernández-Montequin 2007 compared two doses of recombinant human epidermal growth factor, 75 µg and 25 µg.

Six trials compared growth factors versus other interventions (with or without co-interventions): silver sulphadiazine (Afshari 2005); insulin (Chen 2004); oxidized regenerated cellulose/collagen biomaterial (Kakagia 2007); moisture-regulating dressing (Landsman 2010); oasis wound matrix (Niezgoda 2005); and actovegin (Tsang 2003).

The mean age of participants was 59.1 years (standard deviation (SD) ± 4.16), and most were male (66.6% (SD ± 16.1%)). Ten trials included participants with type 1 and type 2 diabetes mellitus (Driver 2006; Fernández-Montequin 2007; Fernández-Montequin 2009; Hanft 2008; Hardikar 2005; Jaiswal 2010; Landsman 2010; Niezgoda 2005; Viswanathan 2006; Wieman 1998a). Eighteen trials did not report the type of diabetes mellitus explicitly (Afshari 2005; Agrawal 2009; Bhansali 2009; Chen 2004; d’Hemecourt...
Trials included participants with target foot ulcers at nine different sites (fore-foot, mid-foot, hind-foot, internal and external edge, sole, plantar surface, ankle). Six trials included participants with neuropathic ulcers (Hardikar 2005; Lyons 2007; Richard 1995; Robson 2002; Steed 1992; Steed 1996). The remaining 22 trials did not report the cause of the foot ulcers. Generally, the trials were conducted in the out-patient (ambulatory) setting.

Location of trials

The trials were conducted in ten countries: three in China (Chen 2004; Tan 2008; Tsang 2003); two in Cuba (Fernández-Montequin 2007; Fernández-Montequin 2009); one in Greece (Kakagia 2007); five in India (Agrawal 2009; Bhansali 2009; Hardikar 2005; Jaiswal 2010; Viswanathan 2006); one in Iran (Afshari 2005); one in Italy (Saldalamacchia 2004); one in Japan (Uchi 2009); and eleven in the USA (d’Hemecourt 1998; Driver 2006; Hanft 2008; Holloway 1993; Landsman 2010; Robson 2002; Steed 1992; Steed 1995a; Steed 1995b; Steed 1996; Wieman 1998a). One trial was conducted in both Canada and the USA (Niezgoda 2005), and another in both France and Italy (Richard 1995).

Trial methods

All trials were conducted using the parallel group trial design. Eighty-two per cent of the trials (23/28) were conducted without reporting an a priori estimation of sample size. Trials were small with sample sizes ranging from 13 to 382 participants, with a median sample size of 60 and a mean of 87 (± SD 76). Fourteen trials had follow-up periods of less than 20 weeks (range five to 18 weeks) (Afshari 2005; Agrawal 2009; Driver 2006; Fernández-Montequin 2007; Fernández-Montequin 2009; Hanft 2008; Jaiswal 2010; Kakagia 2007; Richard 1995; Saldalamacchia 2004; Steed 1995b; Tan 2008; Uchi 2009; Viswanathan 2006). Thirteen trials had a follow-up of 20 weeks or more (range 20 weeks to 26 weeks) (Bhansali 2009; d’Hemecourt 1998; Hardikar 2005; Holloway 1993; Landsman 2010; Lyons 2007; Niezgoda 2005; Robson 2002; Steed 1992; Steed 1995a; Steed 1996; Tsang 2003; Wieman 1998a). One trial did not report length of follow-up (Chen 2004). In the trials, the units of randomisation and analysis were the participants. In terms of assessing the stage of the ulcer - trials variously used Wagner’s classification, the University of Texas Diabetic classification, or the International Association Enterostomal Therapy classification for (Appendix 3). Appendix 9 shows the methods for assessing ulcer dimension.

Excluded studies

We excluded nine studies for the following reasons: case reports (Acosta 2006; Miller 1999; Tuyet 2009); non-RCTs (Aminian 2000; Saad Setta 2011); case series (Embil 2000; Hong 2006); and phase IV study (post-marketing surveillance study) (Mohan 2007; Yera-Alos 2013). See the Characteristics of excluded studies table.

Ongoing trials

We identified six ongoing trials (NCT00521937; NCT00709514; NCT00915486; NCT00926068; NCT01060670; NCT01098357). Full details are shown in the table of Characteristics of ongoing studies.

Studies awaiting classification

Four citations are ‘Awaiting classification’ (Gomez-Villa 2014; Morimoto 2013; Singla 2014; Young 1992; see Characteristics of studies awaiting classification for details).

Risk of bias in included studies

The risk of bias in the included trials is summarised in Figure 2 and Figure 3, and detailed in the Characteristics of included studies table.
Figure 2. Risk of bias graph: review authors’ judgements about each risk of bias item presented as percentages across all included studies.
Figure 3. Risk of bias summary: review authors' judgements about each risk of bias item for each included study.
Allocation

Random sequence generation
The risk of bias arising from the method of generation of the allocation sequence was considered to be low in eleven trials (Chen 2004; Driver 2006; Fernández-Montequin 2007; Fernández-Montequin 2009; Holloway 1993; Jaiswal 2010; Kakagia 2007; Niezgoda 2005; Robson 2002; Steed 1995a; Uchi 2009). The remaining 17 trials had unclear risk of bias for this domain.

Allocation concealment
The risk of bias arising from the method of allocation concealment was considered to be low in two trials (Niezgoda 2005; Uchi 2009). The remaining 26 trials had an unclear risk for this domain.

Blinding
The risk of bias due to lack of blinding of participants and personnel was rated as low in 11 trials (Fernández-Montequin 2007; Fernández-Montequin 2009; Hardikar 2005; Holloway 1993; Steed 1992; Steed 1995a; Steed 1995b; Steed 1996; Uchi 2009; Viswanathan 2006; Wieman 1998a). The risk of bias of performance bias was high in the remaining 17 trials.

In four trials outcome assessment was clearly reported as blinded, and detection bias was considered to be low (Fernández-Montequin 2007; Hanft 2008; Richard 1995; Uchi 2009). Blinding of outcome assessors was unclear or not performed in the remaining 24 trials, so the risk of detection bias was considered to be high.

Incomplete outcome data
Risk of attrition bias was rated as low in six trials (Richard 1995; Robson 2002; Steed 1995a; Steed 1995b; Uchi 2009; Viswanathan 2006), but high in the remaining 22 trials.

Selective reporting
Risk of selective outcome reporting bias was rated as low in three trials (Agrawal 2009; Driver 2006; Richard 1995), two trials was rated as having unclear risk (Lyons 2007; Niezgoda 2005), and rated as high in the remaining 23 trials. It was mainly due to these trials neither measured nor reported complete wound closure or safety data.

Other potential sources of bias
Risk of other bias was rated as high in all 28 trials due to bias in the presentation of data or design bias.

Accordingly, all trials were considered to have an overall high risk of bias.

Effects of interventions
See: Summary of findings for the main comparison Any growth factor compared with placebo or no growth factor for diabetic foot ulcer

Primary outcomes
Complete wound closure (defined as 100% epithelialisation or skin closure without drainage)

Any growth factor versus placebo or no growth factor
Meta-analysis of 12 trials showed that growth factors, when considered as a group, increased the incidence of complete wound healing compared with placebo or no growth factor (345/657 (52.51%) versus 167/482 (34.64%); RR fixed-effect model 1.51 95% CI 1.31 to 1.73; I² = 51%, low quality evidence due to limitations in design, execution or both, and inconsistency) (d’Hemecourt 1998; Hanft 2008; Hardikar 2005; Holloway 1993; Jaiswal 2010; Richard 1995; Robson 2002; Saldalamacchia 2004; Steed 1992; Steed 1995a; Uchi 2009; Viswanathan 2006; Wieman 1998a). See Analysis 1.1. Figure 4 shows a funnel-plot of this meta-analysis.
Subgroup analysis of trials with follow-up of less than 20 weeks compared to trials with follow-up of 20 weeks or longer

Meta-analysis of five trials with follow-up of less than 20 weeks shows uncertainty due to imprecision (small sample size and low rate of events) in the proportion of complete wound healing comparing any growth factor versus placebo or no growth factor (102/167 (61.07%) versus 60/119 (50.42%); RR 1.24, 95% CI 1.00 to 1.55; $I^2 = 57%$; P value 0.05) (Jaiswal 2010; Richard 1995; Saldalamacchia 2004; Uchi 2009; Viswanathan 2006). Meta-analysis of seven trials with a follow-up of 20 weeks or longer showed an increase in the incidence of complete wound healing comparing any growth factor versus placebo or no growth factor (243/490 (49.59%) versus 107/363 (29.47%); RR 1.65, 95% CI 1.38 to 1.98; $I^2 = 34%$) (d’Hemecourt 1998; Hanft 2008; Hardikar 2005; Holloway 1993; Steed 1992; Steed 1995a; Wieman 1998a). The subgroup test showed high inconsistency between the two groups ($I^2 = 73.5%$, P value 0.05). See Analysis 2.1.

Subgroup analysis by type of growth factor

One trial comparing autologous growth factor versus placebo or no growth factor showed inconclusive results regarding complete wound closure due to high imprecision (2/7 (28.57%) versus 1/7 (14.28%); RR 2.0, 95% CI 0.23 to 17.34; P value 0.53) (Saldalamacchia 2004). Meta-analysis of two trials comparing platelet-derived wound healing formula versus placebo showed a significant increase in the likelihood of participants with complete wound healing receiving growth factor (36/56 (64.28%) versus 7/27 (25.92%); RR 2.45, 95% CI 1.27 to 4.74, $I^2 = 0%$) (Holloway 1993; Steed 1992). Meta-analysis of five trials showed that recombinant human platelet-derived growth factor (beacplermin) increased the proportion of the participants with complete wound healing compared with placebo (205/428 (47.89%) versus 109/335 (32.53%); RR 1.47, 95% CI 1.23 to 1.76, $I^2 = 74%$) (d’Hemecourt 1998; Hardikar 2005; Jaiswal 2010; Steed 1995a; Wieman 1998a). Meta-analysis of two trials comparing recombinant human basic fibroblast growth factor versus placebo or no growth factor showed inconclusive results regarding proportion of participants with complete wound healing (60/106 (56.60%) versus 27/59 (45.76%); RR 1.23, 95% CI 0.88 to 1.72, $I^2 = 62%$ P value 0.22) (Richard 1995; Uchi 2009). One trial comparing recombinant human epidermal growth factor versus placebo showed an increase in the incidence of complete wound healing using growth factor (25/29 (86.28%) versus 14/28 (50%); RR 1.72, 95% CI 1.16 to 2.57) (Viswanathan 2006). One trial compar-
ing recombinant human vascular endothelial growth factor versus placebo showed no clear evidence of a difference regarding complete wound closure (15/29 (51.72%) versus 9/26 (34.61%); RR 1.49, 95% CI 0.79 to 2.82; P value 0.21) (Hanft 2008). The subgroup test showed no significant difference between the two groups (I^2 = 0%; P value 0.55). However, the quality of the evidence showed in this subgroup analysis should be considered either low or very low. It is due to severe imprecision (wide confidence intervals) based on small sample size and low number of event (complete wound closure), inconsistency and limitations of design and execution of these trials. See Analysis 3.1.

Sensitivity analysis taking attrition into consideration

Eight of the 12 trials combined for this outcome reported the exact number of participants with missing data in the intervention and the control groups. These trials involved 1043 participants (d’Hemecourt 1998; Hanft 2008; Hardikar 2005; Holloway 1993; Steed 1995a; Uchi 2009; Viswanathan 2006; Wieman 1998a).

‘Best-worst case’ scenario

In a best-worst case scenario analysis where none of the drop-outs/participants were lost from the experimental arm, but all of the drop-outs/participants lost from the control arm experienced the outcome, including all randomised participants in the denominator, meta-analysis of eight trials showed a higher likelihood of complete wound healing in the participants receiving any growth factor compared with those exposed to placebo or no growth factor (417/607 (68.69%) versus 142/436 (32.56%); RR 2.09, 95% CI 1.81 to 2.41; I^2 = 57%; P value 0.00001).

‘Worst-best case’ scenario

In a worst-best case scenario analysis (all drop-outs/participants lost from the experimental arm, but none from the control arm experienced the outcome, including all randomised participants in the denominator) we did not find clear evidence of a difference in the proportion of participants assigned to any growth factor with complete wound healing compared with placebo or no growth factor (318/607 (52.38%) versus 218/436 (50%); RR 1.05, 95% CI 0.93 to 1.19; I^2 = 60%; P value 0.43).

A test for subgroup differences showed a significant difference (I^2 = 98.2%; P value 0.0001). See Analysis 4.1.

Individual growth factor versus active control

There is inconclusive evidence of a difference between autologous growth factor and oxidized regenerate cellulose/collagen biomaterial regarding complete wound healing (4/34 (11.76%) versus 2/17 (11.76%); RR 1.00, 95% CI 0.20 to 14.93; P value 1.00) (Kakagia 2007). One trial reported inconclusive effects when recombinant human platelet-derived growth factor (becaplermin) was compared with OASIS Wound Matrix for achieving complete wound healing (10/36 (27.77%) versus 18/37 (48.64%); RR 0.57, 95% CI 0.31 to 1.06; P value 0.08) (Niezgoda 2005). There is not conclusive results when recombinant human epidermal growth factor was compared with silver sulphadiazine for reaching complete wound healing (7/30 (23.33%) versus 2/20 (10%); RR 2.33, 95% CI 0.54 to 10.11; P value 0.26) (Afshari 2005). There was a higher proportion of complete wound healing in participants allocated to recombinant human epidermal growth factor than those receiving actovegin (32/42 (76.19%) versus 8/19 (42.10%); RR 1.81, 95% CI 1.04 to 3.15; P value 0.04) (Tsang 2003).

Lower limb amputation (minimum of one toe)

No trials described the extent of the amputation (Fernández-Montequin 2007; Fernández-Montequin 2009; Holloway 1993; Tsang 2003).

Any growth factor versus no growth factor

Meta-analysis of two trials showed no clear difference in number of lower limb amputations for growth factors, considered as a group, compared with placebo or no growth factor (19/150 (12.66%) versus 12/69 (17.39%); RR fixed-effects model 0.74, 95% CI 0.39 to 1.39; I^2 = 0%; P value 0.34, low quality evidence due to limitation in design, execution or both, and imprecision) (Fernández-Montequin 2009; Holloway 1993). See Analysis 1.2.

Individual growth factor versus active control

One trial comparing recombinant human epidermal growth factor versus actovegin showed no clear evidence of a difference regarding the incidence of lower limb amputation (2/42 (4.76%) versus 12/19 (10.52%); RR 0.45, 95% CI 0.07 to 2.98; P value 0.41) (Tsang 2003). Meta-analysis of two trials comparing two doses of recombinant human epidermal growth factor, 75 µg and 25 µg, showed no clear difference regarding lower limb amputation (15/76 (19.73%) versus 16/66 (24.24%); RR 0.82, 95% CI 0.44 to 1.52; I^2 = 0%; P value 0.52) (Fernández-Montequin 2007; Fernández-Montequin 2009).

Time to complete healing of the diabetic foot ulcer

Fifteen trials assessed time to complete healing of the diabetic foot ulcer. However, no trial reported hazard ratios or information that would allow us to calculate it. Most trials did not state explicitly that all participants achieved complete healing (Bhansali 2009; Chen 2004; d’Hemecourt 1998; Driver 2006; Fernández-Montequin 2007; Fernández-Montequin 2009; Hanft 2008; Hardikar 2005; Holloway 1993; Niezgoda 2005; Robson 2002; Steed 1995a; Steed 1995b; Viswanathan 2006; Wieman 1998a), see Appendix 10 for details.
Secondary outcomes

Ulc er-free days following treatment for diabetic foot ulcers (free from any recurrence)

One trial comparing recombinant human vascular endothelial growth factor (29 participants) versus placebo (26 participants) showed inconclusive difference in terms of ulcers-free days following treatment (HR 0.64, 95% CI 0.14 to 2.94 P value 0.56) (Hanft 2008).

Quality of life

None of the included trials addressed quality of life.

Adverse events

Any growth factor versus placebo or no growth factor

Meta-analysis of four trials reporting number of participants with events showed no clear evidence of a difference between all growth factors when considered as a group compared with placebo or no growth factor in terms of adverse events (non-serious and serious) (109/232 (46.98%) versus 63/153 (41.17%); RR 0.98, 95% CI 0.79 to 1.22; I² = 0%; P value 0.85, low quality evidence) (Fernández-Montequin 2009; Hanft 2008; Hardikar 2005; Holloway 1993). See Analysis 1.4.

Individual growth factor versus placebo or no growth factor

One trial comparing recombinant human basic fibroblast growth factor (becaplermin) with placebo reported adverse events as follows: “0.65 events per patient (N = 26) in arginine-glycine-aspartic acid peptide matrix with placebo” (Steed 1995b). One trial showed no clear difference in overall adverse events when recombinant human platelet-derived growth factor (becaplermin) was compared with placebo (31/61 (50.81%) versus 34/57 (59.64%); RR 0.85, 95% CI 0.61 to 1.18; P value 0.34) (Steed 1995a).

One trial comparing recombinant human platelet-derived growth factor versus placebo reported an incidence of serious adverse events similar across comparison groups (25%, 30% and 24% either recombinant human platelet-derived growth factor 30 µg/g or 100 µg/g, and placebo, respectively (Wieman 1998a). Meta-analysis of two trials comparing recombinant human platelet-derived growth factor (becaplermin) with placebo showed no clear difference between treatment groups in terms of: infection (35/95 (36.84%) versus 28/127 (22.04%); RR 1.57, 95% CI 0.37 to 6.71, I² = 88%; P value 0.54); cellulitis (11/165 (6.66%) versus 17/127 (13.38%); RR 0.49, 95% CI 0.24 to 1.02, I² = 0%; P value 0.06); peripheral oedema (9/165 (5.45%) versus 16/127 (12.59%); RR 0.44, 95% CI 0.20 to 0.96, I² = 0%; P value 0.04); pain (17/165 (10.30%) versus 16/125 (12.8%); RR 0.78, 95% CI 0.41 to 1.49, I² = 0%; P value 0.45); or skin ulceration (14/165 (8.48%) versus 10/127 (7.87%); RR 1.08, 95% CI 0.49 to 2.37, I² = 0%; P value 0.85) (d’Hemecourt 1998; Steed 1995a). See Analysis 6.2 to Analysis 6.6.

Meta-analysis of two trials comparing recombinant human basic fibroblast growth factor with placebo did not find a difference in terms of infection (3/106 (2.83%) versus 3/59 (5.08%); RR 0.77, 95% CI 0.18 to 3.29; I² = 0%; P value 0.72) (Richard 1995; Uchi 2009). Analysis 7.2.

One trial showed no clear evidence of a difference between recombinant basic fibroblast growth factor versus placebo in terms of adverse events (4/97 (4.12%) versus 3/51 (5.88%); RR 0.26, 95% CI 0.02 to 2.83; P value 0.27) (Uchi 2009). One trial showed no clear difference between recombinant human epidermal growth factor group and placebo in terms of any adverse event (65/101 (64.35%) versus 31/48 (64.58%); RR 1.00, 95% CI 0.77 to 1.29; P value 0.98), or any severe adverse event (8/101 (7.92%) versus 2/48 (4.16%); RR 1.90, 95% CI 0.42 to 8.61; P value 0.40) (Fernández-Montequin 2009). One trial comparing recombinant human vascular endothelial growth factor with placebo showed inconclusive results in the incidence of adverse events during the six-week treatment period (14/29 (48.27%) versus 13/26 (50%); RR 0.97, 95% CI 0.56 to 1.65; P value 0.90) or the 12-week observation period (5/26 (19.23%) versus 6/23 (26.08%); RR 0.74, 95% CI 0.26 to 2.10; P value 0.57). This trial also did not show a conclusive difference in terms of serious adverse events during the six-week treatment period (2/29 (6.89%) versus 3/26 (11.53%); RR 0.60, 95% CI 0.11 to 3.30; P value 0.56) or 12-week observation period (3/26 (11.53%) versus 3/26 (11.53%); RR 1.00, 95% CI 0.22 to 4.50; P value 1.00) (Hanft 2008).

Individual growth factor versus active control

One trial comparing recombinant human platelet-derived growth factor (becaplermin) with OASIS Wound Matrix did not find clear evidence of a difference in terms of treatment related events (10/36 (27.77%) versus 17/37 (45.94%); RR 0.60, 95% CI 0.32 to 1.14; P value 0.12) (Niezgoda 2005). One trial comparing different doses of recombinant human epidermal growth factor, 75 µg versus 25 µg, showed no difference in terms of burning sensation (5/23 (21.73%) versus 2/18 (11.11%); RR 1.96, 95% CI 0.43 to 8.94 P value 0.39; 41 participants), or local pain (4/23 (17.39%) versus 3/18 (16.66%); RR 1.04, 95% CI 0.27 to 4.08; P value 0.95; 41 participants) (Fernández-Montequin 2007). One trial showed evidence of a difference in reduction of local wound pain in participants who received recombinant human acidic fibroblast growth factor compared with those who received recombinant human basic fibroblast growth factor (2/104 (1.92%) versus 6/35 (17.14%); RR 0.11, 95% CI 0.02 to 0.53; 9 P value 0.006) (Tan 2008).

DISCUSSION

Growth factors for treating diabetic foot ulcers (Review)

Copyright © 2015 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.
Summary of main results

This Cochrane systematic review of growth factors for treating foot ulcers in people with diabetes included 28 randomised clinical trials that incorporated 2365 participants. Trials evaluated 11 different experimental growth factors compared with several different control interventions. Overall, the trials had a high risk of bias and were underpowered. Most of the trials, 82% (23/28), did not report an a priori sample size estimation. Drug companies sponsored at least 14 of the trials. The trials were conducted in 10 countries (Canada, China, Cuba, France, Greece, India, Iran, Italy, Japan, and the USA). In general the trials were conducted in the out-patient (ambulatory) setting. The reporting of trial participants characteristics was ill-defined with regard to their type of diabetes mellitus and etiology of their diabetic foot ulcer.

Meta-analysis was possible only on six types of experimental growth factors: platelet-derived growth factor, autologous growth factor; platelet-derived wound healing formula, recombinant human platelet-derived growth factor, recombinant human basic fibroblast growth factor, and human epidermal growth factor.

We were able to meta-analyse data on trial participants with complete wound healing. Meta-analysis of 12 trials showed that all growth factors, when considered as a group, seemed to increase the proportion of participants with complete wound healing significantly compared with placebo or no growth factor. The quality of the estimate was qualified as low due to limitations in design and execution of included trials, and inconsistency (Summary of findings for the main comparison).

We were able to meta-analyse data on lower limb amputation (minimum of one toe). One meta-analysis of two trials showed no clear evidence that growth factors, when as considered as a group, reduced the risk of lower limb amputation compared with placebo or no growth factor. Evidence was downgraded to very low due to pitfalls in design and execution of included trials, and a very small sample size and very low number of events (Summary of findings for the main comparison). Another meta-analysis of two trials that compared two doses of recombinant human epidermal growth factor, 75 µg and 25 µg, did not show a significant difference between the two doses.

Eleven trials reported time to complete healing of the diabetic foot ulcer; however, meta-analysis was not possible due to the unique comparisons within each trial, failure to report data, with or without a high rate of withdrawals. One trial comparing recombinant human vascular endothelial growth factor versus placebo showed inconclusive result on ulcer-free days following treatment. Trials did not report data on quality of life. Growth factors compared against placebo or no growth factor showed no difference in terms of any adverse event. However, overall, safety data were poorly reported and adverse events may have been underestimated. Evidence was considered as low due to limitations in design and execution, and low number of event (Summary of findings for the main comparison).

Trials with a 20-week or longer follow-up seemed to be more effective in increasing the number of participants with complete wound closure than trials with a follow-up of less than 20 weeks. However, there was no conclusive difference between these groups.

We conducted a subgroup analysis of trials by type of growth factor. There was an inconclusive difference between growth factor versus placebo or no growth factor in terms of the number of participants with complete wound closure. This is could be due to small sample size and low number of events.

In terms of complete wound closure we found a clear difference between the ‘best-worse case’ scenario and the ‘worst-best case’ scenario in sensitivity analyses that took attrition into consideration. It should be interpreted as inconsistency due to missing data.

Overall completeness and applicability of evidence

This Cochrane review found evidence suggesting that growth factors might be useful for increasing complete wound closure of foot ulcers in people with diabetes, though this conclusion is based on randomised clinical trials with a high risk of bias due to pitfalls in design and execution of the included trials. Therefore, and based on GRADE findings, future research are a need to know with a better certainty the clinical benefits of growth factors for treating diabetic foot ulcers. Furthermore, the safety profile of all the growth factors is unclear.

The results in this review are based on data from trials that included a broad range of participants with different co-morbidities, who received different treatment approaches. That heterogeneity downgraded the quality of evidence. We cannot rule out that the calculations of the potential effects have been overestimated due to poor methodological quality (bias risks, design, analysis and the small information size. Therefore, these three variables, i.e., high heterogeneity, pitfalls in methodology, and small sample size and low number of events, even after meta-analysis, depleted the quality of evidence. Furthermore, we cannot exclude an underestimation of harms. A caveat concerning the safety of recombinant human platelet-derived growth factor (beacplermin) has been outlined recently; this relates to the risk of cancer in people who use three tubes or more compared to that in non-users (FDA 2008; Papanas 2010). However, an observational study reported that this growth factor does not appear to increase the risk of cancer or cancer mortality (Ziyadeh 2011), though further high-quality data are clearly needed.

Quality of the evidence

GRADE assessments were conducted on outcomes of both meta-analysis and non-pooled trials. None of the trials was graded as providing strong evidence, primarily because of small sample sizes (even after meta-analysis) which generate wide confidence intervals.
with low precision of estimate of the intervention effects, and the high risk of bias due to a lack of adequate randomisation methods, lack of blinding, high attrition, and unclear reporting of outcomes. Quality of evidence also had to be downgraded due to inconsistency. We cannot reject a potential detection bias - wound healing is a fairly subjective outcome - where is there is no blinded outcome assessment or unclear for this, even though due to clear definition of complete wound closure.

See Summary of findings for the main comparison for complete assessment and rationale for ratings.

This review assessed the impact of missing data on the effect of intervention in increasing the proportion of participants with complete wound closure (Analysis 4.1) using best/worst and /best case scenarios. If the amount of missing data is large, the conclusion on the difference between the comparison groups is not valid (Hollis 1999). This Cochrane review found a significant subgroup difference comparing all trials, best/worst and /best case scenarios (Analysis 4.1).

This Cochrane review has identified the following issues that should be considered when planning future trials: inconsistent information concerning the healing percentage of wound closure definition provided by trial reports, differences in definitions of outcomes, and inconsistency of reported outcomes need to be avoided. Trials should adopt an agreed set of core outcomes for each medical condition (Clarke 2007). This approach may reduce the impact of outcome reporting bias (Kirkham 2010).

The impact of outcome reporting bias may be reduced by adopting the recommendations of The Patient-Centered Outcomes Research Institute (PCORI) (PCORI 2012). This organisation was established by United States Congress as an independent, non-profit organisation, created to conduct research to provide information about the best available evidence to help patients and their healthcare providers make more informed decisions. PCORI’s research is intended to give patients a better understanding of the prevention, treatment and care options available, and the science that supports those options (Gabriel 2012; Basch 2012; PCORI 2012; Selby 2012).

**Potential biases in the review process**

There is a group of biases called significance-chasing biases (Ioannidis 2010), which includes publication bias, selective outcome reporting bias, selective analysis reporting bias, and fabrication bias. Publication bias represents a major threat to the validity of systematic reviews, particularly in reviews that include small trials. However, this Cochrane review has a low risk of publication bias due to the meticulous trial search that was performed, and the fact that we emailed the main authors of a number of the trials identified. Selective outcome reporting bias operates through suppression of information about specific outcomes and has similarities to publication bias of whole studies or trials, in that ‘negative’ results remain unpublished (Ioannidis 2010). We were surprised to find how few times amputations or mortality were reported in the trials. This Cochrane review found that 75% of the included randomised clinical trials had high risks of selective outcome reporting. For example, adverse events were not reported (Afshari 2005; Bhansali 2009; Chen 2004; Jaiswal 2010; Kakagia 2007; Landsman 2010; Saldalamacchia 2004; Steed 1992; Steed 1996; Tan 2008; Tsang 2003), or were poorly reported in a total of 16 trials (Hardikar 2005; Holloway 1993; Lyons 2007; Viswanathan 2006; Wieman 1998a). These 16 trials incorporated 55% of the randomised participants (1289/2365) included in this review. This review found no evidence of asymmetry of the funnel plot for complete wound closure (Figure 4).

**Agreements and disagreements with other studies or reviews**

The results of our review are similar to the findings from other systematic reviews (Buchberger 2010; O’Meara 2000) and a narrative review of complete closure of diabetic foot ulcer using growth factors (Wieman 1998b).

**AUTHORS’ CONCLUSIONS**

**Implications for practice**

There is insufficient evidence from RCTs to recommend or refute the use of growth factors in treating diabetic foot ulcers. The results are based on the results of 28 RCTs with a high risk of bias. There is a paucity of information for other main clinical outcomes such as lower limb amputation, time to complete healing of the diabetic foot ulcer and ulcer-free days following treatment for diabetic foot ulcers (free from any recurrence). There is an absence of information on mortality, and quality of life. In addition, adverse events data remain unclear. Therefore, prescription of growth factors for treating people with diabetic foot ulcers can not be supported or rejected until new evidence from a large, high-quality trial becomes available and alters this conclusion.

**Implications for research**

This systematic review has identified the need for well-designed, adequately powered RCTs to assess the benefits and harms of growth factors with complete wound closure, lower limb amputation, and adverse events as the primary outcomes. Since epidemiological studies have connected to the recombinant human platelet-derived growth factor (becaplermin) to a five-fold increase in cancer mortality in people who used more than three tubes of it compared to non-users, potential risk needs to be ruled out in large randomised clinical trials before wider use can be recommended. The trials should be designed according to the SPIRIT statement.
(Chan 2013), and reported according to the CONSORT statement for improving the quality of reporting of efficacy; the trials should also provide better reports of harms/adverse events encountered during their conduct (Ioannidis 2004; Moher 2010; Schulz 2010). Future trials should be planned following the Foundation of Patient-Centered Outcomes Research recommendations (Basch 2012; Gabriel 2012; McKinney 2012). Potential trials should also include clinical outcomes such as, incidence of lower limb amputation (minimum of one toe, with the extent of amputation being specified, and data the incidence of different extents of amputation also reported separately), time to complete healing of the diabetic foot ulcer, quality of life, ulcer-free days following treatment for diabetic foot ulcers (free from any recurrence), and adverse events.

|                                          | i) Intervention group: 50% (14/28) (number of ulcers not reported) |
|                                          | ii) Control group: 50% (14/28) (number of ulcers not reported) |
|                                          | 2. Age (years, mean ± standard deviation) |
|                                          | i) Intervention group (54.38 ± 8.7) |
|                                          | ii) Control group (56.24 ± 8.75) |
|                                          | 3. Gender (male) |
|                                          | i) Intervention group: 64.3% (9/14) |
|                                          | ii) Control group: 71.4% (10/14) |
|                                          | 4. Inclusion criteria |
|                                          | i) ≥ 30 years of age |
|                                          | ii) A glycaemic target of HbA1c ≤ 7.0%, but HbA1c > 7.0% was not an exclusion criterion |
iii) Ulcer stage I, II, III or IV according to the Wagner (1981) classification
iv) Foot ulcer duration of > 3 months, free of infection, with an adequate lower-limb blood supply demonstrated by a TcPO2 ≥ 30 mmHg
v) Free of, or a moderate degree of, peripheral vascular disease

5. Exclusion criteria
i) Active neoplastic disease
ii) Diagnosis of active infection
iii) Those who had received immunosuppressive therapy during the preceding 3 months
iv) Those with liver disease, pulmonary tuberculosis, thyroid disorder, uraemia, alcoholism, or renal insufficiency, and those undergoing vascular reconstruction or receiving steroid or anticoagulant therapy

### Interventions
1. Intervention group: recombinant human platelet-derived growth factor (becaplermin) (0.01%) gel/day.
2. Control: placebo gel, no further details provided

### Co-interventions: both groups received debridement, dressing, pressure relief and glycaemic control

### Outcomes
Healing: participants categorised as complete responders, partial responders, non-complete responders (p 84)

### Notes
1. A priori sample size estimation: not provided
2. Sponsor: not reported

### Bhansali 2009

**Methods**
- Parallel-design (2 arms)  
- Country: India  
- Follow-up period: 20 weeks  
- Unit of randomisation: participant  
- Analysis unit: participant

**Participants**
- Randomised: 20 (24 ulcers)  
  - Intervention group: 50% (10/20) (13 ulcers)  
  - Control group: 50% (10/20) (11 ulcers)  
- Age (years, mean ± SD)  
  - Intervention group: 51.7 ± 13.6  
  - Control group: 49.5 ± 8.83  
- Gender (male)  
  - Intervention group: 70% (7/10)  
  - Control group: 50% (5/10)  
- Inclusion criteria  
  - > 20 years of age with type 1 or 2 diabetes  
  - At least 1 neuropathic plantar ulcer of Wagner grade 2 without X-ray evidence of osteomyelitis  
  - ABPI > 0.9  
- Exclusion criteria: not reported

**Interventions**
- Intervention group: recombinant human platelet-derived growth factor (becaplermin) 0.01% gel (once daily)  
- Control: placebo consisting of moist saline (once daily)  
- Co-interventions: debridement at baseline, offloading

**Outcomes**
- Incidence of complete wound closure, duration of complete healing, rate of healing and safety

**Notes**
- A priori sample size estimation: not reported  
- Sponsor: not reported

**d'Hemecourt 1998**

**Methods**
1. Parallel-design (2 arms)
2. Country: USA
3. Study period: 20 weeks
4. Unit of randomisation: participant
5. Analysis unit: participant

**Participants**
1. Randomised: 172
   i) Intervention group 1 (becaplermin): 20% (34/172)
   ii) Intervention group 2 (sodium carboxymethylcellulose (NaCMC)): 41% (70/172)
   iii) Control group: 39% (68/172)
2. Age (years; mean ± standard deviation): overall: 58.3 ± 12.13
   i) Intervention group 1 (becaplermin): 58.5 ± 11.90
   ii) Intervention group 2 (NaCMC): 56.9 ±13.02
   iii) Control group: 59.6 ±11.2
3. Gender (male)
   i) Intervention group 1 (becaplermin): 70.6% (24/34)
   ii) Intervention group 2 (NaCMC): 70.0% (49/70)
   iii) Control group: 79.4% (54/68)
4. Inclusion criteria
   i) Presence of chronic diabetic ulcer on lower extremity for at least 8 weeks prior to the study
5. Exclusion criteria
   i) Osteomyelitis affecting the area of the target ulcer
   ii) Target ulcer area after debridement (measured by multiplying length by width) < 1 cm² or > 10 cm²
   iii) > 3 chronic ulcers present at baseline
   iv) Ulcers resulting from any cause other than diabetes
   v) Use of concomitant medications known to affect wound healing (corticosteroids, chemotherapy, or immunosuppressive agents)
   vi) Women who were pregnant, nursing, or of childbearing potential who were not using an acceptable method of birth control

**Interventions**
1. Intervention groups
   i) Intervention group 1: recombinant human platelet-derived growth factor (becaplermin) gel 100 μg/g (Regranex® Gel 0.01%)
   ii) Intervention group 2: sodium carboxymethylcellulose (NaCMC) aqueous-based gel
2. Control group: good wound care
Co-interventions: all groups received good wound care consisting of initial sharp de-
bridement of ulcers to remove nonviable tissue, daily moist saline dressing changes, offlooding of pressure, and systemic control of infection

| Outcomes | 1. Primary: percentage of participants achieving complete wound closure without drainage or need for dressing  
2. Secondary:  
   i) time to achieve complete wound closure  
   ii) relative ulcer area from baseline to endpoint  
   iii) wound evaluation score (6 parameters: erythema, oedema, purulence, necrotic tissue, fibrin, and drainage) |
| Notes | 1. A priori sample size estimation: not reported  
2. Sponsor: not reported |

#### Selective reporting (reporting bias)

**High risk**

One or more outcomes of interest in the review were reported incompletely so that they could not be entered in a meta-analysis. This trial did not report time to complete wound closure.

#### Other bias

**High risk**

Bias in the presentation of data and design bias, see Appendix 1.

### Driver 2006

#### Methods

1. Parallel-design (2 arms)
2. Country: USA (14 sites)
3. Follow-up: 12 weeks
4. Unit of randomisation: participant
5. Analysis unit: participant

#### Participants

1. Randomised: 72
   i) Intervention group: 56% (40/72)
   ii) Control group: 44% (32/72)
2. Age (years ± SD)
   i) Intervention group: 56.4 ± 10.2
   ii) Control group: 57.5 ± 9.1
3. Gender (male %)
   i) Intervention group: 80% (32/40)
   ii) Control group: 84% (27/32)
4. Inclusion criteria
   i) People with type 1 or type 2 diabetes aged 18-95 years, with an ulcer of at least 4 weeks’ duration
Driver 2006  (Continued)

ii) HbA1c < 12

iii) Index foot ulcer located on the plantar, medial, or lateral aspect of the foot (including all toe surfaces)

iv) Wound area (length x width) measurement between 0.5 cm² and 20 cm²

v) Wounds located under a Charcot deformity had to be free of acute changes and must have undergone appropriate structural consolidation

vi) Index ulcer had to be clinically noninfected (cultures taken, but infection diagnosed through clinical signs and symptoms rather than culture results) and full-thickness without exposure of bone, muscle, ligaments, or tendons (University of Texas Treatment-Based Diabetic Foot Classification System: Grade 1A)

vii) Ulcer free of necrotic debris, foreign bodies, sinus tracts, tunnelling, and undermining after debridement

viii) Comprised of healthy vascularized tissue, and at least 4 cm from any additional wound

ix) Adequate limb perfusion assessed by examination and non-invasive vascular testing, ABPI and toe brachial index

x) Pregnant or lactating women; both men and women had to be willing to use a medically-accepted form of birth control throughout the trial and for 6 months following

5. Exclusion criteria

i) People currently enrolled in another investigational device or drug trial or previously enrolled (within last 30 days) in investigative research of a device or pharmaceutical agent

ii) ≥ 50% decrease in ulcer area during the 7-day screening period

iii) Ulcer due to non-diabetic aetiology

iv) Blood vessels non-compressible for ABPI testing

v) Evidence of gangrene in ulcer or on any part of the foot

vi) Radiographic evidence consistent with diagnosis of acute Charcot foot

vii) Currently receiving or had received radiation or chemotherapy within 3 months of randomisation

viii) Use of topical, oral or IV antibiotic/antimicrobial agents or medications within 2 days (48 hours) of randomisation

ix) Growth factor therapy administered within 7 days of randomisation (e.g. autologous platelet-rich plasma gel, becaplermin, bilayered cell therapy, dermal substitute, extracellular matrix)

x) Screening serum albumin level < 2.5 g/dL

xi) Screening haemoglobin < 10.5 mg/dL

xii) Screening platelet count < 100 x10⁹/L

xiii) Undergoing renal dialysis, known immune insufficiency, known abnormal platelet activation disorders i.e. gray platelet syndrome, liver disease, active cancer (except remote basal cell of the skin), eating/nutritional, haematologic, collagen vascular disease, rheumatic disease, or bleeding disorders

xiv) History of peripheral vascular repair within 30 days of randomisation

xv) Known or suspected osteomyelitis

xvi) Surgical correction (other than debridement) required for ulcer to heal

xvii) Exposed tendons, ligaments, muscle, or bone in Index ulcer

xviii) Known psychological, developmental, physical, emotional, or social disorder, or any other situation that might interfere with compliance with study requirements or
healing of the ulcer, or both

xix) History of alcohol or drug abuse within the year prior to randomisation
xx) Inadequate venous access for blood draw
xxi) Religious or cultural conflict with the use of platelet gel treatment

Interventions

1. Intervention group: platelet-rich plasma gel (AutoloGel™, Cytomedix, Inc, Rockville, Md), frequency of administration not reported
2. Control group: saline gel (Normlgel®, Mölnlycke Health Care, Norcross, Ga), frequency of administration not reported

Co-interventions: cleaning and interim wound assessment of vital signs, offloading orthosis walker

Outcomes

Primary: proportion of participants with a healed wound

Notes

1. A priori sample size estimation: yes (p 72)
2. Sponsor: not reported

**Fernández-Montequin 2007**

**Methods**
1. Parallel-design (2 arms)
2. Country: Cuba (5 sites)
3. Follow-up: 5-8 weeks
4. Unit of randomisation: participant
5. Analysis unit: participant

**Participants**
1. Randomised: 41
   i) Intervention group 1 (rhEGF 75 µg): 56% (23/41)
   ii) Intervention group 2 (rhEGF 25 µg): 44% (18/41)
2. Age (years, mean ± SD)
   i) Intervention group 1 (rhEGF 75 µg): 63 ± 12
   ii) Intervention group 2 (rhEGF 25 µg): 67.5 ± 19.5
3. Gender (male)
   i) Intervention group 1 (rhEGF 75 µg): 52.2%
   ii) Intervention group 2 (rhEGF 25 µg): 56%
4. Inclusion criteria
   i) Diabetic participants (type 1 or 2) of both sexes
   ii) > 18 years
   iii) Grade 3 or 4 foot ulcer according to Wagner’s classification, with high risk of amputation
5. Exclusion criteria
   i) Foot ulcer area ≤ 1 cm²
   ii) Hb < 100 g/l
   iii) Uncontrolled chronic diseases (coronary or heart disease, diabetic coma or ketoacidosis, renal failure defined as a creatinine > 200 µmol/L and oligoanuria)
   iv) Malignancies, psychiatric or neurological diseases that could impair proper reasoning for consent
   v) Pregnancy and nursing

**Interventions**
1. Intervention group 1: intraleosional injections of rhEGF 75 µg (Citoprot-P®; Herber Biotec, Havana, Cuba), in hospital, 3 times/week (alternate days)
2. Intervention group 2: intraleosional injections rhEGF 25 µg (Citoprot-P®; Herber Biotec, Havana, Cuba), in hospital, 3 times/week (alternate days)
Co-interventions: standardised wound care regimen, ulcers were sharply debrided, gangrenous and necrotic tissue removed whenever necessary, and broad-spectrum antibiotics and metabolic control as required

**Outcomes**
Primary: response at 5 to 8 weeks (percentage of ulcer area covered by granulation tissue)
1. Complete (75-100%)
2. Partial (50-75%)
3. Minimal (25-50%)
4. No response (<25%)

Secondary efficacy endpoints
1. Time to obtain complete response
2. Complete healing (no exudates or need of dressing)
3. Prevention of limb amputation
4. Recurrence during 1-year-follow-up

Notes
1. Sample size a priori calculation: yes (pp 335-6)
3. Role of sponsor: financed the study, “the authors received free drug (rhEGF) . . . ” (p 341)
4. Conflict of interest: some authors were employees of the Centre for Biological Research, which is part of the Centre for Genetic Engineering and Biotechnology, Havana network, where rhEGF is produced and the new formulation was developed
5. E-mail was sent to main author

</table>

Quote "Nine patients in the lower EGF dose and placebo groups switched treatment at week 2 and are defined as non healers in further analysis. This design could have some impact on outcome regarding granulation rates at the week 8 visit and closure rates at 1 year follow-up" (p 437)

It is likely that the principle of ITT analysis was violated

### Selective reporting (reporting bias)

| High risk |
| One or more outcomes of interest in the review were reported incompletely so that they could not be entered in a meta-analysis Time-to-complete response was reported using odds ratio (p 435)

### Other bias

| High risk |
| 1. This trial did not report hazard ratios for time to complete wound closure |
| 2. Bias in the presentation of data and design bias, see Appendix 1 |
Hanft 2008

Methods

1. Parallel-design (2 arms)
2. Country: USA (9 sites)
3. Follow-up period: 12 weeks
4. Unit of randomisation: participant
5. Analysis unit: participant

Participants

1. Randomised: 55
   i) Intervention group (telbermin): 53% (29/55)
   ii) Control group (placebo): 47% (26/55)
2. Age (years; mean and range)
   i) Intervention group (telbermin): 59.5 (42-74)
   ii) Control group (placebo): 59.3 (38-81)
3. Gender (male)
   i) Intervention group (telbermin): 66% (19/29)
   ii) Control group (placebo): 69% (18/26)
4. Inclusion criteria
   i) People aged 18-80 years with type 1 or 2 diabetes mellitus
   ii) HbA1c ≤ 12%
   iii) Grade 1A ulcer, as defined by the University of Texas Diabetic Wound Classification
   iv) Chronic ulcer with a duration of ≥ 4 weeks but < 6 months
   v) Ulcer area, following sharp debridement, of 1-4 cm²
   vi) ABPI of 0.6-1.2 on the study foot
   vii) For females of childbearing potential, use of an effective method of contraception
   viii) Subjects with Charcot or another deformity of the study foot were included provided the deformity did not involve the study ulcer
5. Exclusion criteria
   i) Active ulcer infection or cellulitis of any ulcer
   ii) Ulcers with an aetiology unrelated to diabetes
   iii) Active osteomyelitis in the study foot
   iv) Subjects with ulcers related to an incompletely healed amputation wound
   v) Use of any investigational drug/therapy on the study foot within the past month
   vi) Previous use of platelet-derived or other growth factors on the study ulcer within the past 3 months
   vii) Immunosuppressive treatment
   viii) History of neoplasia or current neoplasia (with the exception of non-melanoma skin cancer)
   ix) Proliferative diabetic retinopathy or wet age-related macular degeneration
   x) Connective tissue disease
   xi) Pregnancy or lactation
   xii) Multiple ulcers on the study foot
   xiii) Renal failure (serum creatinine of > 3.0 mg/dL)
   xiv) Poor nutritional status (albumin of < 3.0 g/dL)
   xv) Known hypersensitivity to any ingredients of telbermin, placebo or vehicle including usually inactive substances in the formulation of telbermin or placebo gel
   xvi) Known prior instability likely to affect completion of required study visits during the treatment period
### Interventions
1. **Intervention group:** recombinant human vascular endothelial growth factor (telbermin), 72 µg/cm² over the entire ulcer surface and margins, 3 times/week, for 6 weeks
2. **Control:** placebo (formulated bulk solution without telbermin) in methylcellulose gel for 6 weeks

**Co-interventions:** standard good wound care including periodic sharp debridement at the clinician’s discretion, also offloading

### Outcomes
1. **Primary:**
   i) **Safety:** measured as incidence of clinically significant hypotension (a drop of ≥ 35 mmHg in systolic blood pressure relative to pre-dose level) 60 minutes after application of the study drug during the first week of treatment.
   ii) **Efficacy:** assessed as percentage reduction in total ulcer surface area at day 43 (up to day 49 as the week 7 study visit could occur any time between days 43 and 49 for scheduling flexibility) from baseline (day 1), as determined by quantitative analysis of the planimetric tracings
2. **Secondary**
   i) **Safety:**
      a) incidence of clinical significant ulcer infection, defined as increased discharge and malodorous exudates from the ulcer, fever (≥ 38.6 °C) and white blood cell count > 10000/µl
      b) development of anti-telbermin antibodies
      c) incidence of adverse events
   ii) **Efficacy:**
      a) percentage reduction in total ulcer surface area at days 29 and 84 from baseline (day 1)
      b) incidence of ulcer healing at days 29, 43 and 84
      c) time (days) to complete ulcer healing
      d) time (days) to recurrence for subjects whose ulcers had healed completely before day 84
      e) incidence of increased total ulcer surface area (more than 15%), compared with baseline (day 1)
      f) incidence of a progression in ulcer stage (University of Texas Classification Diabetic Wound Classification)

### Hardikar 2005

---

**Growth factors for treating diabetic foot ulcers (Review)**

Copyright © 2015 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.
### Participants

1. **Randomised:** 113  
   - Treatment group: 55 (48.67%)  
   - Control group: 58 (51.33%)

2. **Age (years mean ± standard deviation (SD))**  
   - Treatment group: 54.5 ± 9.9  
   - Control group: 54.7 ± 9.0

3. **Gender (male)**  
   - Treatment group: 73% (40/55)  
   - Control group: 69% (40/58)

4. **Inclusion criteria**  
   - Type 1 or 2 diabetes mellitus  
   - Age \( \geq 18 \) years but \( \leq 80 \) years  
   - At least 1, but \( < 3 \) full-thickness chronic neuropathic ulcers of at least 4 weeks duration on the lower extremity  
   - Only ulcers categorized as stage III or stage IV (according to the Wound, Ostomy, and Continence Nurses Society)  
   - Ulcers with infection control as determined by a wound evaluation score could be included  
   - Evidence of adequate perfusion of the foot, assessed by colour arterial Doppler ultrasonography

5. **Exclusion criteria**  
   - Arterial venous ulcers  
   - Ulcers caused by osteomyelitis or burns  
   - Poor nutritional status (serum total proteins < 6.5 g/dL)  
   - Persistent infection  
   - Life-threatening concomitant diseases  
   - Deformities like Charcot foot  
   - Chronic renal insufficiency (serum creatinine > 3 mg/dL)  
   - Uncontrolled hyperglycaemia (HbA1c > 12%)  
   - History of use of corticosteroids or immunosuppressants  
   - Hypersensitivity to the gel components of the intervention  
   - Women who were pregnant or nursing  
   - Women of childbearing age who were not taking contraceptives or were not willing to use them

### Interventions

1. **Intervention group:** recombinant human platelet-derived growth factor (becaplermin), 0.01% gel containing 100 \( \mu \)g of experimental drug, daily application  
2. **Control:** placebo, details not reported

Co-interventions: standard wound care regimen consisting of appropriate sharp surgical debridement; daily ulcer cleaning and dressing; and offloading (e.g. crutches or wheelchair), or, where possible, complete bed rest. During this 1-week period, before the baseline visit (visit 2), a regimen of daily wound cleaning and dressing with appropriate non-weight bearing was followed. The use of antidiabetic medication and appropriate use of systemic antibiotics was advised during the treatment period

### Outcomes

1. **Primary:** percentage of participants achieving complete wound closure  
2. **Secondary**  
   - Time to achieve complete wound closure  
   - Percentage reduction in the ulcer surface area at each visit

Funding bias

**Holloway 1993**

**Methods**
1. Parallel-design (4 arms), 2-phase study  
2. Country: USA  
3. Follow-up: 20 weeks  
4. Unit of randomisation: participant  
5. Analysis unit: participant

**Participants**
1. Total randomised participants: unclear  
i) First phase  
a) Randomised: 14  
b) Intervention group: number not specified  
c) Control group: number not specified  
i) Second phase  
a) Randomised: 97 (number of wounds: not specified)  
b) Randomised and treated: 81 (91 wounds)  
c) Randomised and analysed: 70 (77 wounds)  
platelet-derived wound healing formula 0.01 dilution group: 15  
platelet-derived wound healing formula 0.033 dilution group: 13  
platelet-derived wound healing formula 0.1 dilution group: 21  
Control (placebo) group: 21
2. Age of randomised and analysed participants: (mean years): 59.4 to 62.6 years  
3. Gender (male):  
i) platelet-derived wound healing formula 0.01: 73% (11/15)  
ii) platelet-derived wound healing formula 0.033: 77% (10/13)  
iii) platelet-derived wound healing formula 0.1: 81% (17/21)  
iv) Placebo: 67% (14/21)  
4. Inclusion criteria  
i) People with diabetes mellitus with at least 1 chronic, nonhealing diabetic ulcer of 8 weeks duration  
ii) Wounds 500 mm$^3$-50,000 mm$^3$  
5. Exclusion criteria  
i) Wounds possibly containing malignant cells  
ii) Pre-existing diseases or terminal disease  
iii) Pregnant, nursing or of childbearing potential
Interventions

1. Intervention group
   i) First phase: thrombin-induced, platelet-released platelet-derived wound healing formula 0.01 dilution
   ii) Second phase: thrombin-induced, platelet-released platelet-derived wound healing formula (0.01, 0.1, and 0.033 dilutions)
2. Control group:
   i) First phase: physiologic saline solution
   ii) Second phase: isotonic platelet buffer containing 2-[4-(2-hydroxyethyl)piperazin-1-yl]ethanesulfonic acid (HEPES), glucose sodium chloride and potassium chloride (pH 6.6)

Outcomes

Primary: healed (functional assessment points 3 & 4 in original paper):
"3: 100% epithelized; maturing skin with a small amount of drainage; requires protective dressing only
4: 100% epithelized; maturing skin with a small amount of drainage; no dressing required" (p 200)

Notes

1. This trial had 2 phases using 2 random sequence generations:
   i) first phase included the first 14 participants, platelet-derived wound healing formula 0.01 dilution (experimental group) and physiologic saline solution as placebo
   ii) second phase (second randomisation) was conducted to include 2 additional dilutions of platelet-derived wound healing formula (0.1 and 0.033) and a new placebo (isotonic platelet buffer containing 2-[4-(2-hydroxyethyl)piperazin-1-yl]ethanesulfonic acid, glucose sodium chloride and potassium chloride).
2. A priori sample size estimation: not reported
3. Sponsor: Curative Technologies, Inc
4. Role of sponsor: financial

**Kakagia 2007**

**Methods**

1. Parallel-design (3 arms)  
2. Country: Greece  
3. Study period: 8 weeks  
4. Unit of randomisation: participant  
5. Unit analysis: participant

**Participants**

1. Enrolled: 72  
2. Randomised: 51  
   i) Intervention group 1 (oxidized regenerated cellulose/collagen biomaterial): 33.33% (17/51)  
   ii) Intervention group 2 (autologous growth factor delivered by gravitational platelet separation system): 33.33% (17/51)  
   iii) Intervention group 3 (both above interventions): 33.33% (17/51)  
3. Age (years, mean ± standard deviation (SD))
i) Intervention group 1 (oxidized regenerated cellulose/collagen biomaterial): 58 ± 10
ii) Intervention group 2 (Autologous growth factor delivered by gravitational platelet separation system): 57 ± 12
iii) Intervention group 3 (both above interventions): 61 ± 9
4. Gender (male)
i) Global: 43.13% (22/51).
5. Inclusion criteria
i) Diabetic participants with significant soft tissue defects of the foot that had been present for at least 3 months
ii) Target ulcers ≥ 2.5 cm in any dimension after debridement
6. Exclusion criteria
i) Previous treatment with vacuum, hyperbaric oxygen, corticosteroid, immunosuppressive agents, radiation, or growth factors
ii) Anaemia
iii) Presence of cellulitis or venous stasis
iv) Inadequate perfusion determined by toe pulses of < 40
v) Osteomyelitis
vi) Malignancy in the wound
vii) Inability to attend clinics for follow-up

### Landsman 2010

**Methods**
- Randomized, controlled trial, parallel design (2 arms)
- Country study: USA
- Intention to treat: unclear
- Follow up period: 20 weeks
- Unit of randomization: unclear
- Unit of analysis: ulcers

**Participants**
- Randomised: 32, no further details provided
- Age (years)
  - Intervention group (becaplermin plus TheraGauze): 58.1
  - Control group (TheraGauze): 56.2
- Gender (male): not reported
- Inclusion criteria
  1. Forefoot or midfoot ulcer
  2. Wagner grade 1 or 2
  3. Tolerate offloading with healing shoe, fixed ankle walker, or non-weight-bearing
  4. Age 18-70 years
  5. Insulin dependent diabetes mellitus or non insulin dependent diabetes mellitus (IDDM or NIDDM)
  6. HbA1c ≤ 10% of total Hb
  7. Palpable dorsalis pedis and posterior tibial pulses
  8. 1-8 cm² wound surface area
- Exclusion criteria
  1. Active infection, including purulent discharge, cellulitis, or both
  2. Exposed bone
  3. Osteomyelitis associated with ulcer
  4. Dorsal ulcer
  5. Ischaemic ulcers
  6. Evidence of gangrene
- Withdrawal: not reported
### Interventions

1. **Intervention group:** recombinant human platelet-derived growth factor (becaplermin, Regranex 0.01%) daily in accordance with the manufacturer’s recommendations, plus moisture-regulating dressing (TheraGauze®, Soluble systems LLC, Newport News, Virginia)

2. **Control group:** moisture-regulating dressing (TheraGauze®, Soluble systems LLC, Newport News, Virginia) applied directly to the wound surface every other day

Co-interventions: standard wound debridement as needed, offloading with a fixed ankle walker (Royce Medical Diabetic Boot; Ossur Medical, Camarillo, California), and dressing changes every other day

### Outcomes

1. Time to closure (full epithelialisation)

2. Rate of change in wound surface area

### Notes

1. A priori sample size estimation: not reported

2. Sponsor: Soluble systems LLC, Newport News, Virginia

3. Role of the sponsor: sponsor funded the study

4. Conflict of interest: the main author is a paid consultant for Soluble systems LLC

5. Email was sent to the main author requesting data on main outcome

### Lyons 2007

#### Methods

1. Parallel-design (3 arms), 2 phases
2. Country: USA (7 sites)
3. Follow-up period: 6 months
4. Unit of randomisation: participant
5. Analysis unit: participant
6. The study was conducted in 2 phases: phase 1 was an open-label, sequential, dose-escalation design. Phase 2 was a single-blind, randomized, stratified, placebo-controlled pilot study to evaluate the efficacy of the 2 highest dose levels below the maximum tolerated dose (if any, up to 8.5% talactoferrin gel) of topically applied talactoferrin compared with placebo.

#### Participants

1. Randomised: 46
   - i) Intervention group 1 (talactoferrin (recombinant human lactoferrin) 2.5% gel): 32.6% (15/46)
   - ii) Intervention group 2 (talactoferrin (recombinant human lactoferrin) 8.5% gel): 32.6% (15/46)
   - iii) Control group (placebo gel): 34.8% (16/46)
2. Age (years, mean ± standard deviation (SD))
   - i) Intervention group 1 (talactoferrin (recombinant human lactoferrin) 2.5% gel): 58 ± 10
   - ii) Intervention group 2 (talactoferrin (recombinant human lactoferrin) 8.5% gel): 53 ± 15
   - iii) Control group (placebo gel): 56 ± 14
3. Gender (male)
   - i) Intervention group 1 (talactoferrin (recombinant human lactoferrin) 2.5% gel): 93% (14/15)
   - ii) Intervention group 2 (talactoferrin (recombinant human lactoferrin) 8.5% gel): 80% (12/15)
   - iii) Control group (placebo gel): 56% (9/16)
4. Inclusion criteria
   - i) Age:≥ 18 years
   - ii) Diabetes mellitus with HbA1c between 6%-13%
   - iii) Presence of 1 or more diabetic neuropathic foot ulcers at, or below, the ankle that had not healed or decreased in size (≥ 30%) within the prior 4 weeks despite appropriate standard treatment
   - iv) Index ulcer required to be full thickness, extending through the dermis, but without tendon, muscle, joint capsule, or bone exposure, and without sinus tract, with post debridement size of 0.5 to 10 cm²
   - v) Transcutaneous oxygen tension of ≥ 30 mmHg or ABPI ≥ 0.7
5. Exclusion criteria
   - i) Target ulcer from any cause other than diabetes
ii) Signs of clinical wound related infection, including - but not limited to - cellulitis, osteomyelitis, gangrene, or deep tissue infection in the study extremity

iii) Active Charcot’s foot on the limb under study

iv) Prior treatment of the target ulcer with Regranex (Ortho-McNeil Pharmaceutical, Inc, New Brunswick, NJ) within the previous 14 days, or autologous or allogeneic graft, or Dermagraft to the target ulcer within the preceding 4 weeks

| Interventions | 1. Intervention group 1: talactoferrin (recombinant human lactoferrin) 2.5% gel applied topically twice daily for 12 weeks  
2. Intervention group 2: talactoferrin (recombinant human lactoferrin) 8.5% gel applied topically twice daily for 12 weeks  
3. Control group: placebo gel applied topically twice daily for 12 weeks, no details provided about the nature of placebo  
Co-interventions: standard care consisted of:  
1. initial and periodic (as needed) sharp debridement;  
2. twice daily saline dressing change, including cleansing with saline;  
3. offloading using standardised devices (DH Pressure Relief Walkers; Royce Medical, Camarillo, CA);  
4. systemic control of any infection |
| Outcomes | Primary endpoint of phase 2: percentage of participants achieving ≥ 75% closure of the target ulcer |
| Notes | 1. A priori sample size estimation: no  
2. Sponsor: Agennix Inc, Houston, TX, and the National Institute of Arthritis and Musculoskeletal and Skin Diseases of the National Institute of Health  
3. Role of the sponsor: supplied the drugs and placebo for study (p 50) and support in part (p 49) |

### Niezgoda 2005

#### Methods

- Parallel-design (2 arms)
- Study period: 12 weeks
- Follow-up: 6 months
- Country: USA and Canada (9 sites)
- Unit of randomisation: participant
- Analysis unit: participant

#### Participants

- Enrolled: 98
- Randomised: 98
  - Intervention group 1 (OASIS Wound Matrix): 51% (50/98); 37 completed assigned treatment
  - Intervention group 2 (Regranex gel): 49% (48/98); 36 completed assigned treatment
  - Cross-over: “Patients whose wounds were not healing by 12th week were given the option to cross over to the other treatment arm” (p 260). 12 participants in the Regranex Gel group crossed over to receive OASIS, 1 participant healed; 9 participants in the OASIS arm crossed over to receive Regranex Gel, 2 healed
- Age (years, mean ± standard deviation (SD))
  - Intervention group 1 (OASIS Wound Matrix): 58 ± 2.3
  - Intervention group 2 (bepaplermin (Regranex gel)): 57 ± 1.9
- Gender (male)
  - Intervention group 1 (OASIS Wound Matrix): 62% (23/37)
  - Intervention group 2 (bepaplermin (Regranex gel)): 58% (21/36)
- Inclusion criteria
  - ≥18 years
  - Type 1 or type 2 diabetes mellitus
  - Ulcer size 1-49 cm²
  - Ulcer depth required to extend through both the epidermis and dermis
  - Grade I, Stage A (University of Texas classification)
  - Present for >1 month and nonhealing
  - Viable wound bed with granulation tissue
6. Exclusion criteria
   i) Exposed bone, tendon, or fascia
   ii) Clinically defined and documented severe arterial disease
   iii) History of radiation therapy to the ulcer site
   iv) Ulcer of nondiabetic pathophysiology
   v) Receiving corticosteroids or suppression of the immune system
   vi) History of collagen vascular disease malnutrition (albumin < 2.5 g/dL)
   vii) Known allergy to porcine-derived products
   viii) Known hypersensitivity to any component of Regranex Gel (e.g. parabens)
   ix) Religious or cultural objection to the use of porcine products
   x) Uncontrolled diabetes (HbA1c > 12%)
   xi) Previous organ transplant
   xii) Clinically infected ulcer
   xiii) Signs of cellulitis, osteomyelitis, necrotic or avascular ulcer bed
   xiv) Undergoing haemodialysis
   xv) Insufficient blood supply to the ulcer (TcPO2 < 30 mmHg or toe-brachial index < 0.70)
   xvi) Active Charcot or sickle cell disease
   xvii) Received treatment with any other investigational drug or device within the last 30 days
   xviii) Unable to comply with the procedures described in the protocol
   xix) Enrolled in a clinical evaluation for another investigational wound care device or drug

Interventions
1. Intervention group 1: recombinant human platelet-derived growth factor (becaplermin (Regranex gel)), applied topically daily and removed after 12 hours
2. Control group: OASIS Wound Matrix (HEALTHPOINT, Ltd, Fort Worth, TX) applied topically weekly
   Co-interventions: standard wound care, pressure-relief shoes (DH Pressure Relief Shoe; Royce Medical Co, Camarillo, CA)

Outcomes
Primary outcome: incidence of complete wound healing by 12 weeks

Notes
1. A priori sample size estimation: not reported
2. Sponsor: Cook Biotech Incorporated, West Lafayette, IN, and DH Pressure Relief Shoe; Royce Medical Co, Camarillo, CA
3. Role of sponsors: provided the study supplies, including treatment products, dressing supplies, and pressure-relief shoes
4. Conflict of interest: one trial author is a research scientist with Cook Biotech Incorporated

Risk of bias

<table>
<thead>
<tr>
<th>Bias</th>
<th>Authors' judgement</th>
<th>Support for judgement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Random sequence generation (selection bias)</td>
<td>Low risk</td>
<td>Quote “were assigned to a treatment group using a centralized computer system” (p 259)</td>
</tr>
</tbody>
</table>
### Allocation concealment (selection bias)
- **Risk:** Low risk
- **Description:** Quote “individual investigators were blinded to the size of the block” (p 259)

### Blinding of participants and personnel (performance bias)
- **Risk:** Unclear risk
- **Description:** Insufficient information provided to permit a judgment of ‘low risk’ or ‘high risk’

### Blinding of outcome assessment (detection bias)
- **Risk:** Unclear risk
- **Description:** Insufficient information provided to permit a judgment of ‘low risk’ or ‘high risk’

### Incomplete outcome data (attrition bias)
- **Risk:** High risk
- **Loss:** Lost post randomisation (treated): total = 26% (25/98)
  1. Experimental group: 26% (13/50)
  2. Control group: 25% (12/48)
  3. Imbalance between groups: 1%
- **Reasons for loss:**
  1. Infection: Intervention group = 23% (3/13); Control group = 17% (2/12)
  2. Mortality: Intervention group = 8% (1/13); Control group = 0% (0/12)
  3. Non-adherence to follow up visits: Intervention group = 31% (4/13); Control group = 58% (7/12)
  4. Hospitalisation and related to the study or target wound: Intervention group = 23% (3/13); Control group = 0% (0/12)
  5. Tendon/ bone exposure: Intervention group = 8% (1/13); Control group = 0% (0/12)
  6. Withdrew consent: Intervention group = 0% (0/13); Control group = 17% (2/12)
  7. Received other wound care therapy: Intervention group = 8% (1/13); Control group = 8% (1/12)

### Selective reporting (reporting bias)
- **Risk:** Unclear risk
- **Description:** One or more outcomes of interest in the review were reported incompletely so that they could not be included in a meta-analysis

### Other bias
- **Risk:** High risk
- **Description:** Bias of presentation data, see Appendix 1
- **Funding bias**
### Methods
1. Parallel-design (2 arms)
2. Country: France and Italy
3. Study period: 18 weeks
4. Unit of randomisation: participant
5. Analysis unit: participant

### Participants
1. Randomised: 17
   - i) Intervention group (basic fibroblastic growth factor): 53% (9/17)
   - ii) Control group (physiologic saline solution): 47% (8/17)
2. Age (years, mean ± SD)
   - i) Intervention group (basic fibroblastic growth factor): 61.9 ± 10.0
   - ii) Control group (physiologic saline solution): 63.6 ± 7.9
3. Gender (male)
   - i) Intervention group (basic fibroblastic growth factor): 100% (9/9)
   - ii) Control group (physiologic saline solution): 87.5% (7/8)
4. Inclusion criteria
   - i) Typical, chronic, nonhealing neuropathic ulcer on the plantar surface of the foot
   - ii) Grade 1-3, according to Wagner’s classification
   - iii) After mechanical excision, the largest part of the wound had to measure more than 0.5 cm
   - iv) Vibration perception threshold higher than 30 V either at the big toe or at the medial malleolus
5. Exclusion criteria: not reported

### Interventions
1. Intervention group: basic fibroblastic growth factor (Farmitalia Carlo Erba, Milano, Italy) 50 µg (5 µg/ml), applied once a day on an in-patient basis during the first 6 weeks. During the last 12 weeks, it was applied twice a week, and participants were allowed to return home if ulcer progression was satisfactory
2. Control group: placebo (normal saline), applied once a day on an in-patient basis during the first 6 weeks. During the last 12 weeks, it was applied twice a week, and participants were allowed to return home if ulcer progression was satisfactory

Co-interventions:
1. Intensive insulin therapy using 3 subcutaneous injections a day or continuous subcutaneous insulin infusion maintained during the entire experimental period
2. Participants were totally non weight-bearing

### Outcomes
1. Healing
2. Improvement
3. No progression
4. Worsening
5. Ulcer perimeter reduction (% of initial perimeter)
6. Time for 50% healing (weeks)

### Notes
1. A priori sample size estimation: not reported
2. Sponsor: Farmitalia Carlo Erba Laboratory, Milano, Italy; P Dang
3. Role of sponsor: supported the study; reviewed the manuscript

</tr>
</tbody>
</table>

### Outcomes

**Primary**

1. Proportion of participants with complete ulcer closure at or before week 21
2. Percentage of ulcer area reduction by week 21

**Secondary**

1. Proportion of participants with complete closure of the ulcer at each weekly visit
2. Percentage of ulcer area reduction at each weekly visit
3. Time to wound closure
4. 3-month follow-up assessment of durability of wound closure
5. Safety
Notes

1. A priori sample size estimation: not reported
2. Sponsor: Genzyme Corporation
3. Role of sponsor: created computer-generated treatment randomisation lists, generated the coded labelling key, provided editorial comment and review, program management, management of the clinical trial

### Saldalamacchia 2004

**Methods**
1. Parallel-design (2 arms)
2. Country: Italy
3. Follow-up period: 5 weeks
4. Unit of randomisation: participant
5. Analysis unit: participant

**Participants**
1. Randomised: 14
   - i) Intervention group: 50% (7/7)
   - ii) Control group: 50% (7/7)
2. Age (years, mean ± SD)
   - i) Intervention group: 61.1 ± 9.4
   - ii) Control group: 58.1 ± 7.8
3. Gender (male)
   - i) Intervention group: 57.14% (4/7)
   - ii) Control group: 28.57% (2/7)
4. Inclusion criteria
   - i) Diabetic participant
   - ii) Grade 2 or 3 ulcer according to Wagner, lasting for at least 8 weeks, and without signs of infection
5. Exclusion criteria: not reported

**Interventions**
1. Intervention: topic application of autologous platelet gel plus standard care plus, frequency not reported
2. Control: standard care

**Outcomes**
- Reduction rate (%)
  - Complete healing or reduction of at least 50%

**Notes**
1. This trial was reported as a letter to editor
2. A priori sample size estimation: not reported
3. Sponsor: not reported

| Incomplete outcome data (attrition bias) | Unclear risk | Insufficient reporting of attrition/exclusions to permit a judgement of ‘low risk’ or ‘high risk’ (i.e. no reasons provided for missing data) |
| Selective reporting (reporting bias) | High risk | This trial did not report safety data |
| Other bias | High risk | Bias of presentation data, see Appendix 1 |

### Steed 1992

**Methods**
1. Parallel-design (2 arms)
2. Follow-up: 20 weeks
3. Country: USA
4. Unit of randomisation: participant
5. Analysis unit: participant

**Participants**
1. Randomised: 13
   i) Intervention group (platelet-derived wound healing formula, homologous): 54% (7/13)
   ii) Control group (placebo): 46% (6/13)
2. Age: (years, ± SD)
   i) Intervention group (platelet-derived wound healing formula, homologous): 58.7 ± 12.4
   ii) Control group (placebo): 54.2 ± 12.9
3. Gender (male)
   i) Intervention group (platelet-derived wound healing formula, homologous): 71.4% (5/7)
   ii) Control group (placebo): 67% (4/6)
4. Inclusion criteria
   i) A neurotrophic ulcer of the lower extremity that had not healed after at least 8 weeks of standard treatment
   ii) Diabetes mellitus
   iii) Platelet count ≥ 100,000/mm³
   iv) TcPO₂ > 30 mmHg
5. Exclusion criteria
   i) Clinical signs of infection such as erythema, induration, tenderness, fever, or chills

**Interventions**
1. Intervention group: platelet-derived wound healing formula was applied to a cotton gauze sponge and placed on the ulcer in the evening. The intervention was prepared from blood donors.
2. Control group: placebo (normal saline) was applied to a cotton gauze sponge and placed on the ulcer in the evening

Co-interventions: normal cotton gauze applied to the wound for the next 12 hours; participants were supplied with a half-shoe (IPOS North American Niagara Fakks, NY) that transferred the weight to their heel and could be used for balance, they also had access to wheel-chairs, crutches, or walkers to avoid weight-bearing; debridements...
### Outcomes

1. Functional assessment (healing)
2. Reduction in wound volume

### Notes

1. A priori sample size estimation: not reported
2. Sponsor: Curative technologies, Inc
3. Role of sponsor: supported part of this research
4. Half shoes IPOS North American, Niagara Falls, NY

**Imbalance in wound area (mm²) and initial volume (mm³) at baseline**
Steed 1995a

Methods

1. Parallel-design (2 arms)
2. Country: USA (10 sites)
3. Follow-up period: 20 weeks
4. Unit of randomisation: participant
5. Analysis unit: participant

Participants

1. Randomised: 118 (118 ulcers)
   i) Intervention group (recombinant human platelet-derived growth factor): 51.7% (61/118) (61 ulcers)
   ii) Control group: 48.3% (57/118) (57 ulcers)
2. Age (years, mean)
   i) Intervention group (recombinant human platelet-derived growth factor): 63.2
   ii) Control group: 58.3
3. Gender (male)
   i) Intervention group (recombinant human platelet-derived growth factor): 86.8% (53/61)
   ii) Control group: 80.7% (46/57)
4. Inclusion criteria
   i) At least 19 years of age
   ii) At least one ulcer between 1-100 cm² in area
   iii) Free of infection according to clinical examination and radiographs
   iv) Adequate arterial blood supply assessed by measuring TcPO2 of ≥ 30 mmHg on the dorsum of the foot, or at the margin of the ulcer if the ulcer was on the plantar surface
5. Exclusion criteria
   i) Women of childbearing potential
   ii) Nursing mothers
   iii) Hypersensitivity to any component of the study gel
   iv) > 3 ulcers
   v) Ulcers caused by large-vessel arterial ischaemia, venous insufficiency, pressure, or necrobiosis lipoidica diabeticorum
   vi) Osteomyelitis, malignant or terminal disease
   vii) Alcohol or substance abuse
   viii) People who had participated in a clinical trial of an investigational drug or device within the previous 30 days
   ix) Thermal, electrical, or radiation burn wounds at the site of the target ulcer
   x) People receiving corticosteroids, immunosuppressive agents, radiation therapy or chemotherapy
   xi) Vascular reconstruction during the previous 8 weeks

Interventions

1. Intervention group: recombinant human platelet-derived growth factor (becaplermin) (rhPDGF-BB (Chiron Corp, Emeryville, CA; Johnson and Johnson, New Brunswick, NJ)) applied to the target ulcer once a day at a dose calculated to approximate 2.2 µg of rhPDGF-BB/cm² ulcer area; 12 hours later the residual gel was removed by mild irrigation with saline
2. Control group: placebo gel administered in the same way as the intervention gel. Details of the nature of the placebo were not reported
Co-interventions: a saline-moistened gauze dressing was placed over the target ulcer and gel, and the foot wrapped with a roll of gauze. Pressure relief for the target ulcer achieved
by means of crutches, wheelchairs, orthotic shoes, or other methods. Sharp debridement could be performed at each office visit if the investigator thought it was necessary.

| Outcomes | 1. Primary: complete healing (100% wound closure with no drainage present and no dressing required)  
2. Secondary:  
i) Time to complete wound closure  
ii) Percentage reductions in area of target ulcers |
| Notes | 1. A priori sample size estimation: not reported  
2. Sponsor: RW Johnson Pharmaceutical Research Institute (Raritan, NJ)  
3. Role of sponsor: the sponsor prepared the computer-generated randomizations schedule for each centre before study initiation, and was responsible for the conduct of the trial and all analyses |

### Tan 2008

#### Methods

1. Parallel-design (2 arms)
2. Country: China
3. Follow-up period: 6 weeks
4. Unit of randomisation: participant
5. Analysis unit: participant

#### Participants

1. Number enrolled: not reported
2. Randomised: 139
   - Intervention group 1 (rhaFGF): 104 (75%)
   - Intervention group 2 (rhbFGF): 35 (25%)
3. Age (mean years (range)): 52.2 ± 17.31 (18-75), information not reported by comparison group
4. Gender: not reported
5. Inclusion criteria
   - Chronic skin wound without other growth factor treatments (definition of “chronic state” was not reported)
   - Skin wounds of ≥ 2 cm diameter through the full skin thickness
   - Wound unhealed after at least 8 weeks of routine treatments
6. Exclusion criteria: not reported

---

*Growth factors for treating diabetic foot ulcers (Review)*  
*Copyright © 2015 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.*
### Interventions

1. Intervention group 1: rhαFGF 100 U/0.1 ml/cm² dissolved in normal saline solution and applied topically
2. Intervention group 2: rhβFGF 100 U/0.1 ml/cm² dissolved in normal saline solution and applied topically

Co-interventions: sterile cotton dressing without antibiotics

### Outcomes

Outcomes were not described explicitly as primary end points. Quote “after 6-week treatment, the wounds were divided into four categories: complete healing, significant healing if more than 50% of the wound are had healed; effective healing, if 20-50% of the wound area had healed; ineffective healing, if less than 20% of the wound had healed” (p 434)

### Notes

1. A priori sample size estimation: not reported
2. Sponsor: National Natural Science Foundation, Ministry of Education Incubation Foundation Technology Innovative Project, Program of New Century Excellent Talents in University, Zhejiang Provincial Program for the Cultivation of high-level Innovative Health Talents, Juvenile Diabetes Research Foundation, and Wenzhou Medical College for the Chinese-American Research Institute for Diabetic Complications
3. Role of sponsors: to provide grants

### Tsang 2003

#### Methods

1. Parallel-design (3 arms)
2. Country: China (Diabetes Ambulatory Care Centre)
3. Follow-up period: 24 weeks
4. Unit of randomisation: participant
5. Analysis unit: participant

#### Participants

1. Randomised:48.03% (61/127 enrolled)
   i) Intervention group 1 (Actovegin plus recombinant human epidermal growth factor 0.02%): 34.4% (21/61)
   ii) Intervention group 2 (Actovegin plus recombinant human epidermal growth factor 0.04%): 34.4% (21/61)
   iii) Control group (Actovegin 5%): 31.2% (19/61)
2. Age (years)
   i) Intervention group 1: 68.76 ± 10.45
   ii) Intervention group 2: 62.24 ± 13.68
   iii) Control group: 64.37 ± 11.67
3. Gender (male)
   i) Intervention group 1: 61.9% (13/21)
   ii) Intervention group 2: 28.57% (6/21)
   iii) Control group: 52.63% (10/19)
4. Lost before randomisation: total = 51.96% (66/127). Losses due to:
   i) wound healing
   ii) ulcer above malleoli
   iii) ulcer grade ≥ 3
   iv) ABPI < 0.7
   v) refused consent
5. Inclusion criteria
   i) Ulcer, Wagner grade 1 or 2
   ii) Ulcer located below the ankle
   iii) Ulcer with adequate perfusion, as indicated by an ABPI ≥ 0.7
6. Exclusion criteria
   i) Very poor sugar control
   ii) Ulcers with severity ≥ grade 3

#### Interventions

1. Intervention group 1: daily local application of Actovegin plus 0.02% recombinant human epidermal growth factor, covered with sterile gauze
2. Intervention group 2: daily local application of Actovegin plus 0.04% recombinant human epidermal growth factor, covered with sterile gauze
3. Control group: daily local application of Actovegin 5% cream only, covered with sterile gauze
4. Co-interventions: standard wound care consisted of debridement of necrotic tissue and...
**Outcomes**  
Complete healing defined as full epithelialisation of the wound with an absence of discharge.

**Notes**  
1. A priori sample size estimation: not reported  
2. Sponsor: Bio-Click Technologies Ltd, Hong Kong  
3. Role of sponsor: provided recombinant human epidermal growth factor  
4. Actovegin is a protein free calf blood extract (NYCOMED Austria) (p 1857)

Funding bias  
This was the first trial by this clinical group that assessed recombinant human epidermal growth factor, however, it did not investigate safety |
### Methods

1. Parallel-design (3 arms)
2. Country: Japan
3. Follow-up period: 8 weeks
4. Unit of randomisation: participant
5. Analysis unit: participant

### Participants

1. Randomised: 150
   i) Intervention 1 group (basic fibroblast growth factor 0.001%): 32.7% (49/150), 1 participant withdrew consent before starting treatment
   ii) Intervention 2 group (basic fibroblast growth factor 0.01%): 33.3% (50/150), 1 participant did not receive growth factor as ulcer healed before starting treatment
   iii) Control group (placebo): 34.0% (51/150)
2. Age (years, mean ± SD)
   i) Intervention 1 group (basic fibroblast growth factor 0.001%): 61.0 ± 13.0
   ii) Intervention 2 group (basic fibroblast growth factor 0.01%): 59.8 ± 13.8
   iii) Control group (placebo): 60.2 ± 11.7
3. Gender (male)
   i) Intervention 1 group (basic fibroblast growth factor 0.001%): 66.6% (32/48)
   ii) Intervention 2 group (basic fibroblast growth factor 0.01%): 71.4% (35/49)
   iii) Control group (placebo): 72.5% (37/51)
4. Inclusion criteria
   i) ≥ 20 years of age
   ii) Attending physicians selected a targeted ulcer in presence of multiple ulcers
   iii) Ulcers measuring < 900 mm², not reaching the periosteum (Wagner grade 2)
   iv) ABPI at rest ≥ 0.9 in participants with no palpable pulsation in either artery
5. Exclusion criteria
   i) Severe artery calcification due to maintenance hemodialysis or diabetes
   ii) Malignant tumour or history of malignant tumour
   iii) History of hypersensitivity to basic fibroblast growth factor
   iv) Women with confirmed or suspected pregnancy; nursing women; women who desired to become pregnant during the trial
   v) Patients receiving oral administration or injection of adrenocortical steroid (equivalent to > 20 mg/day of prednisolone)

### Interventions

1. Intervention 1: 5 puffs of basic fibroblastic growth factor at 0.001% (equivalent to 3 µg of basic fibroblastic growth factor) sprayed 5 cm from the target ulcer once a day, for 8 weeks
2. Intervention 2: 5 puffs of basic fibroblastic growth factor at 0.01% (equivalent to 30 µg of basic fibroblastic growth factor) sprayed 5 cm from the target ulcer once a day, for 8 weeks
3. Control: 5 puffs placebo (characteristics not reported) sprayed 5 cm from the target ulcer once a day for 8 weeks

Co-interventions: appropriate treatments to control blood glucose levels

### Outcomes

Primary outcomes:
1. Ulcer shrinkage
2. Safety
Notes

1. A priori sample size estimation: yes (p 463)
2. Sponsor: Kaken Pharmaceutical Co, Ltd
3. Role of sponsor: data collection and pre-specified statistical analysis

| Methods          | 1. Parallel-design (2 arms)  
|                 | 2. Phase III trial  
|                 | 3. Country: India  
|                 | 4. Follow-up period: 15 weeks  
|                 | 5. Unit of randomisation: participant  
|                 | 6. Analysis unit: participant  
| Participants    | 1. Randomised: 60  
|                 | i) Intervention group (recombinant human epidermal growth factor): 50% (30/60)  
|                 | ii) Control group: 50% (30/60)  
|                 | 2. Age (years): not reported  
|                 | 3. Gender (male): not reported  
|                 | 4. Inclusion criteria  
|                 | i) Target ulcers 2-50 cm² in area  
|                 | ii) People available for the 15-week study period who could adhere to the treatment regimen  
|                 | iii) Healthy men or women aged 18-65 years at the time of consent  
|                 | iv) Women of non-child bearing potential (e.g. surgically sterilised), or, if of child bearing potential, must have a negative pregnancy test, or have used adequate contraceptive precautions (as confirmed by the investigator) 30 days prior to screening and the baseline visit, and agreed to continue such precautions up to week 15  
|                 | v) Controlled diabetes mellitus (types 1 and 2) and foot ulcers  
|                 | vi) Ulcers that remained open without healing for more than 2-3 weeks (irrespective of the ambulatory treatment administered)  
|                 | vii) ABPI reading ≥ 0.75  
|                 | 5. Exclusion criteria  
|                 | i) Ulcer ≥ Wagner grade 3  
|                 | ii) Those with life-threatening gastrointestinal, hepatic, renal, endocrine, hematological, or immunologic disorder, or serious cardiac failure (New York Heart Association Grades 3 and 4)  
|                 | iii) Any of the following factors: hypertension grade 3; known case of hypersensitivity to the ingredient(s); uncontrolled diabetes mellitus (type 1 or 2), diabetic ketoacidosis or coma  
|                 | iv) Pregnant women and nursing mothers  
|                 | v) Past history of, or current, acute or chronic autoimmune disease  
|                 | vi) Chronic alcohol abuse (40 mL/day for at least 6 months)  
|                 | vii) Treatment known to impair wound healing, including but not limited to: corticosteroids, immunosuppressive drugs, cytotoxic agents, radiation therapy, and chemotherapy, within 1 month prior to the initial visit  
|                 | viii) Use of any marketed, investigational, or herbal medicine or non-registered drug for wounds or burns in the past 6 months  
|                 | ix) Clinically relevant abnormal haematology or biochemistry values (in the opinion of the investigator)  
|                 | x) Any criteria that, in the opinion of the investigator, suggest non-compliance with the study  
|                 | xi) Evidence of systemic or local infection, such as purulent drainage, osteomyelitis, or nonviable tissue that cannot be removed by debridement  
|                 | xii) Treatment with a dressing containing any other growth factors or other
biological dressings within the 30 days preceding the screening visit

xiii) Participation in another clinical study within the 30 days preceding the screening visit or during the study

| Interventions | 1. Intervention group: topical application of recombinant human epidermal growth factor gel twice daily until the wound healed or until the end of week 15, whichever was earlier
2. Control group: topical application of placebo (water based) gel twice daily until the wound healed or until the end of week 15, whichever was earlier
Co-interventions: normal dose of insulin prescribed; oral and intravenous antibiotics for prevention of infection

| Outcomes | 1. Percentage of healing
2. Duration of healing
3. Quality of healing and epithelisation

| Notes | 1. Trial did not report the baseline characteristics of the groups
2. A priori sample size estimation: not reported
3. Sponsor: Bharat Biotech International Limited, Hyderabad, India
4. Role of sponsor: financial support
5. Conflict of interest: main author was paid an investigator's fee for conducting the study, another author is a consultant for the company that provided the study supplies and that supported study financially

| Risk of bias | Authors' judgement | Support for judgement |
| Bias | | |
| Random sequence generation (selection bias) | Unclear risk | Insufficient information provided to permit a judgment of 'low risk' or 'high risk' |
| Allocation concealment (selection bias) | Unclear risk | Insufficient information provided to permit a judgment of 'low risk' or 'high risk' |
| Blinding of participants and personnel (performance bias) All outcomes | Low risk | Quote “the tubes containing either rhEGF or placebo were similar” |
| Blinding of outcome assessment (detection bias) All outcomes | Unclear risk | Insufficient information provided to permit a judgment of 'low risk' or 'high risk' |
| Incomplete outcome data (attrition bias) All outcomes | Low risk | Lost: 5% (3/60); Intervention group = 1; Control group = 2 |
| Selective reporting (reporting bias) | High risk | One or more outcomes of interest in the review were reported incompletely so that they could not be entered in a meta-analysis Quote "The recorded adverse events were
1 case of rash, 3 cases of pain, and 2 cases of skin irritation” (p. 4/14)
This trial did not report adverse event data according to comparison group

Other bias
High risk
Design bias and bias of presentation bias, see Appendix 1
Funding bias: main author was paid an investigator’s fee for conducting the study, another author is a consultant for the company that provided the study supplies and that supported study financially

Wieman 1998a

Methods
1. Parallel-design (3 arms)
2. Country: USA (23 sites)
3. Follow-up period: 20 weeks
4. Unit of randomisation: participant
5. Analysis unit: participant

Participants
1. Randomised: 382
   i) Intervention 1 (recombinant human platelet-derived growth factor 30 µg/g): 34.6% (132/382)
   ii) Intervention 2 (recombinant human platelet-derived growth factor 100 µg/g): 32.2% (123/382)
   iii) Control group (placebo): 33.2% (127/382)
2. Age (years, means ± SD)
   i) Intervention 1 (recombinant human platelet-derived growth factor 30 µg/g): 58 ± 11.3
   ii) Intervention 2 (recombinant human platelet-derived growth factor 100 µg/g): 57 ± 11.5
   iii) Control group (placebo): 58 ± 11.8
3. Gender (male)
   i) Intervention 1 (recombinant human platelet-derived growth factor 30 µg/g): 62% (82/132)
   ii) Intervention 2 (recombinant human platelet-derived growth factor 100 µg/g): 67% (82/123)
   iii) Control group (placebo): 72% (91/127)
4. Inclusion criteria
   i) Aged ≥ 19 years with type 1 or type 2 diabetes
   ii) At least 1 full thickness (stage III or IV, as defined in the International Association of Enterostomal Therapy guide to chronic wound staging chronic ulcer of the lower extremities. If > 1 lower-extremity ulcer present, the target ulcer was the one that, in the opinion of the investigator, would take the longest time to heal with good wound care practice
   iii) Target ulcer present for at least 8 weeks despite previous treatment
   iv) TcPO2 on the limb with the target ulcer ≤ 30 mmHg
5. Exclusion criteria
   i) Osteomyelitis present in the area of the target ulcer
   ii) Target ulcer area < 1 cm² or > 40 cm² after debridement
   iii) Sum of the areas of all ulcers present > 100 cm²
   iv) Ulcers resulting from any cause other than diabetes (e.g. electrical, chemical, or radiation insult)
   v) Concomitant diseases (e.g. connective tissue disease), treatment (e.g. radiation therapy), or medication (e.g. corticosteroids, chemotherapy, or immunosuppressive agents) that would present safety hazards or interfere with evaluation of the study medication
   vi) Women who were pregnant, nursing, or of childbearing potential and not using either an intrauterine device or oral contraception
   vii) People with cancer

Interventions

1. Intervention group 1: topically applied recombinant human platelet-derived growth factor gel (becaplermin, 30 µg/g), twice daily, morning and evening
2. Intervention group 2: topically applied recombinant human platelet-derived growth factor gel (becaplermin, Regranex Gel 0.01%, 100 µg/g), twice daily, morning and evening
3. Control: topically applied placebo gel, twice daily, morning and evening

Co-intervention: standardised regimen of good wound care

Outcomes

Primary
1. Percentage of participants that achieved complete healing within the 20-week study period
2. Safety

Secondary: time required to achieve complete healing

Notes

1. A priori sample size estimation: not reported
2. Sponsor: not reported

Risk of bias

### Blinding of outcome assessment (detection bias)

| All outcomes | Unclear risk | Insufficient information provided to permit a judgment of 'low risk' or 'high risk' |

### Incomplete outcome data (attrition bias)

| All outcomes | Unclear risk | Lost post randomisation: total = 19% (73/382)  
1. Intervention group 1 = 21% (28/132)  
2. Intervention group 2 = 17% (21/123)  
3. Control group = 19% (24/127)  
Reasons  
1. Lost to follow up: Intervention group 1 = 1/28; Intervention group 2 = 1/21; Control group = 2/24  
2. Adverse events: Intervention group 1 = 17/28; Intervention group 2 = 13/21; Control group = 13/24  
3. Non compliance: Intervention group 1 = 4/28; Intervention group 2 = 3/21; Control group = 3/24  
4. Protocol violation: Intervention group 1 = 2/28; Intervention group 2 = 2/21; Control group = 3/24  
5. Other: Intervention group 1 = 4/28; Intervention group 2 = 2/21; Control group = 3/24 |

### Selective reporting (reporting bias)

| High risk | One or more outcomes of interest in the review were reported incompletely so they could not be entered in a meta-analysis |

### Other bias

| High risk | Quote "the time to complete healing, defined as the number of days until the patients achieved a functional assessment score of 1, was analyzed using Cox's proportional hazards model" (p 824)  
Design bias and bias of data presentation, see Appendix 1 |

**Abbreviations**

- ABPI = ankle-brachial pressure index
- CT-102 = thrombin-induced platelet-released platelet-derived wound healing formula
- Hb = haemoglobin
- HbA1c = glycated haemoglobin
- IAET = The International Association of Enterostomal Therapists (now known as the Wound, Ostomy, Continence Nurses' Society (WOCN))
- ITT = intention to treat (analysis)
IV = intravascular
rhaFGF = recombinant human acidic fibroblast growth factor
rhbFGF = recombinant human basic fibroblast growth factor
rhEGF = recombinant human epidermal growth factor
TcPO2 = transcutaneous oxygen tension

</table>
Notes
1. Data extracted from abstract
2. A priori sample size estimation: no
3. Sponsor: not reported
4. This trial reported these results:
   i) high dose group: complete healing (5/14)
   ii) low dose group and placebo: complete healing: 1/11
   iii) Quote: “no significant differences in median healing rates were found”
5. This trial did not report safety data, however, the authors stated “topical PDGF is well tolerated”
6. It is unclear what the trial authors meant by ‘high dose’ and ‘low dose’

Abbreviation
PDGF = platelet-derived growth factor

Characteristics of ongoing studies  [ordered by study ID]

NCT00521937

Methods
1. Allocation: randomised
2. Endpoint classification: efficacy study
3. Intervention model: parallel assignment
4. Masking: single blind (outcomes assessor)
5. Primary purpose: treatment
6. Country: France

Participants
1. Enrolled: 388
2. Inclusion criteria
   i) Age ≥ 18 years
   ii) Documented, stable type 1 or 2 diabetes mellitus (confirmed by HbA1c at least every 4 months)
   iii) Neuropathic foot ulcer located on the plantar surface of the forefoot
   iv) Ulcer surface area 1-15 cm² (after mechanical debridement of the ulcer)
   v) Palpable pulse evidenced on both feet (presence of dorsalis pedis pulse and posterior tibial pulse)
   or in absence of one pulse, an SPI by Doppler > 0.9 on the target limb
   vi) Presence of diabetic foot ulcer for at least 4 weeks prior to enrolment
   vii) Ulcer extending through the dermis without exposure of muscle, tendon, bone, or joint capsule
3. Exclusion criteria
   i) Typical Charcot’s foot
   ii) Decrease or increase in the size of the ulcer by ≥ 50% during the run-in period
   iii) Presence of osteitis (eq Br osteomyelitis) at the inclusion visit (evidenced with a radiological lesion facing the wound (bone erosion or disappearance of the cortical bone))
   iv) Clinical evidence of PEDIS* grade 3, or 4 infection at the inclusion visit
   v) People who cannot have/use an offloading method
| Interventions | Intervention: Dermagen®  
Control: Conventional treatment |
|---------------|-------------------------------|
| Outcomes      | 1. Primary outcome measure: complete wound closure at week 12: time-frame = 12 weeks; not designated as a safety issue  
2. Secondary outcome measure: time to complete wound healing: time-frame = 24 weeks; not designated as a safety issue |
| Starting date | January 2009 (date of first enrolment) |

**NCT00709514**

| Trial name or title | A phase II, double-blind, placebo-controlled clinical evaluation of DCB-WH1 in healing of chronic diabetic foot ulcers |
| Methods            | 1. Allocation: randomised  
2. Endpoint classification: safety/efficacy study  
3. Intervention model: parallel assignment  
4. Masking: double blind (subject, caregiver, investigator, outcomes assessor)  
5. Primary purpose: treatment  
6. Country: Taiwan |
**Participants**

1. Enrolled: 50
2. Inclusion criteria
   i) ≥ 20 years with diabetes mellitus (type 1 or 2) and a cutaneous ulcer on the foot that has been present for at least 2 weeks
   ii) Grade 1 target ulcer according to a modified Wagner system, which includes wounds involving the epidermis, the dermis, the hypodermis or the subcutaneous fat but not the tendon or joint capsule. The thickness of these layers should be approximately 0.2-8 mm and wounds should have an area of 3-15 cm² post debridement
   iii) ABPI ≥ 0.80
   iv) Study ulcer should show "infection control" as judged by the investigator
   v) Free of any necrotic or infected soft and bony tissue
   vi) Signed informed consent form
3. Exclusion criteria
   i) Ulcers caused by venous or arterial insufficiency, osteomyelitis
   ii) Poor nutritional status (albumin < 3 g/dl), poor diabetic control (HbA1c > 10%), anaemia (Hb < 10 g/dl), leukocyte count < 1000/mm³
   iii) Requiring prostaglandin treatment
   iv) Requiring treatment with corticosteroids, immunosuppressive or chemotherapeutic agents, radiotherapy
   v) Presence of necrosis, purulence or sinus tracts that cannot be removed by debridement
   vi) Presence of connective tissue disease, renal failure (eGFR < 30 ml/min/1.73 m²), abnormal liver function (AST, ALT > 2.5 x upper limit of normal range), malignancy
   vii) Vascularisation surgery performed < 8 weeks before entry into the study
   viii) History of cerebrovascular events, coronary intervention (stent or CABG) or myocardial infarction, within 6 months prior to study
   ix) Female patient with a positive pregnancy test, or breastfeeding, or unwilling to use appropriate contraceptive methods during study

**Interventions**

1. Experimental intervention: 1.25% DCB-WH1 ointment topically applied twice daily
2. Placebo intervention: no details reported

**Outcomes**

Primary outcome measure: incidence of complete ulcer closure: time-frame = 12 weeks; designated as a safety issue

**Starting date**

May 2008 (date of first enrolment)

**Source(s) of monetary support:** Oneness Biotech Co, Ltd

### NCT00915486

**Trial name or title**  
A randomized, multi-center, controlled, parallel group, dose finding study of the efficacy and safety of topically applied I-020201 as an adjunct to good standard-of-care versus good standard-of-care alone in patients with chronic diabetic foot ulcers

**Methods**  
1. Allocation: randomised  
2. Endpoint classification: safety/efficacy study  
3. Intervention model: parallel assignment  
4. Masking: double blind (subject, caregiver, investigator, outcomes assessor)  
5. Primary purpose: treatment  
6. **Country:** Czech Republic, Germany, Hungary, Romania, Russian Federation, Serbia

**Participants**  
**Enrolled:** 210  
1. **Inclusion criteria**  
   i) Age \( \geq \) 18 years  
   ii) Provided written informed consent  
   iii) Women of childbearing potential with a negative result from pregnancy test at screening who agree to use an acceptable birth control method (hormonal or IUD), or abstinence, throughout the trial  
   iv) Type 1 or type 2 diabetes mellitus with HbA1c \( < \) 12%  
   v) Only 1 diabetic foot ulcer on the foot to be treated, on or below the ankle  
2. **Exclusion criteria**  
   i) Pregnant or breast-feeding  
   ii) Known or suspected allergies to any of the components of the I-020201  
   iii) Uncontrolled anaemia (Hb < 9 g/dL in women and < 10 g/dL in men)  
   iv) Hypoalbuminaemia (albumin < 3 g/dL)  
   v) Overly infected target ulcer (as judged by investigator)  
   vi) Highly exuding wounds (wounds that require a daily dressing change)  
   vii) Osteomyelitis  
   viii) Systemic infections  
   ix) Acute Charcot foot and severe chronic Charcot deformity  
   x) ABPI < 0.7 or ankle systolic pressure < 70 mmHg  
   xi) One of the following:  
      a) monophasic or biphasic flow (with loss of reverse flow) in either foot artery, or a toe on Doppler waveform analysis on the dorsalis pedis and posterior tibial arteries  
      b) brachial index < 0.7  
      c) TcPO2 < 40 mmHg  
   xii) Suspicion, presence or history of systemic or local cancer or tumour of any kind

**Interventions**  
1. **Group 1:** Good Standard of Care: Experimental (GSoC): twice per week  
2. **Group 2:** GSoC + vehicle (topical fibrin as an adjunct to GSoC twice per week)  
3. **Group 3:** GSoC + I-020201 (33 µg) topical as an adjunct to GSoC twice per week  
4. **Group 4:** GSoC + I-020201 (100 µg) topical as an adjunct to GSoC twice per week  
5. **Group 5:** GSoC + I-020201 (300 µg) topical as an adjunct to GSoC twice per week
### NCT00915486 (Continued)

**Outcomes**

1. Primary outcome: percentage reduction in ulcer surface area: time-frame = 4 weeks after start of treatment
2. Secondary outcomes
   i) Changes in systemic PDGF-AB and antibody levels against TG-PDGFAB and aprotinin: time-frame: 1, 4, 12, 16 and 20 weeks after start of treatment
   ii) Changes in vital signs, body weight, physical examination and laboratory parameters: time-frame: throughout the study and 28 weeks after start of treatment
   iii) Incidence of complete wound closure (full re-epithelialisation with confirmation 4 weeks afterwards): time-frame = 12 and 16 weeks after start of treatment
   iv) Incidence of complete wound closure (full re-epithelialisation with confirmation 4 weeks afterwards): time-frame = whole study period (28 weeks after start of treatment)
   v) Incidence of participants with ulcer recurrence: time-frame = up to 16 and 28 weeks after start of treatment
   vi) Incidence of treatment failure defined as < 30% decrease in ulcer size: time-frame = after 8 weeks of treatment
   vii) Incidence of treatment-related AEs (systemic and at the target ulcer) and all AEs/SAEs: time-frame = whole study period
   viii) Time to complete wound closure (full re-epithelialisation with confirmation 4 weeks afterwards): time-frame = at any time during the study

### NCT00926068

**Trial name or title**

Safety and efficacy of HO/03/03 10 µg in the treatment of plantar neuropathic diabetic foot ulcers (Truheal)

**Methods**

1. Allocation: randomised  
2. Endpoint classification: safety/efficacy study  
3. Intervention model: parallel assignment  
4. Masking: double blind (subject, investigator)  
5. Primary purpose: treatment  
6. Country: USA
## Participants

1. **Enrolled:** 196

2. **Inclusion criteria**
   
   i) Age 18-80 years, extremes included
   
   ii) Diagnosed with diabetes mellitus type 1 or 2
   
   iii) A documented single, target, non-healing, plantar neuropathic diabetic foot ulcer with a minimal duration of 4 weeks prior to giving informed consent
   
   iv) Ulcer size at randomisation: Wagner grade 1, 2.0-10 cm² extremes included, or Wagner grade 2, 1.0-10 cm² extremes included
   
   v) Single target ulcer on the study foot: Wagner grade 1 or 2 (does not involve abscess or osteomyelitis)
   
   vi) Target ulcer area decreased by ≤ 30%, or ≤ 0.1 cm/week edge healing rate measured, between post-debridement values at screening and at randomisation, if debridement clinically indicated
   
   vii) HbA1c ≤ 12%
   
   viii) Ankle to Brachial Index (ABI) on study foot: 0.7 ≤ ABI ≤ 1.2 or ABI > 1.2 and toe pressure > 50 mm Hg (ABI measured by Doppler; toe blood pressure measured by toe cuff)
   
   ix) Diabetic neuropathy confirmed by neurological testing
   
   x) Participants available for entire study period, and able and willing to adhere to protocol requirements
   
   xi) Signed informed consent form prior to any study protocol-related procedure

3. **Exclusion criteria**

   i) Medical history, current or within the last 2 years, of abuse of alcohol, barbiturates, benzodiazepines, amphetamines, narcotics, cocaine, psychoactive drugs or other substances that interfere with treatment compliance
   
   ii) Use of growth factors, skin graft or participation in an investigational study within 30 days prior to the start of the screening period
   
   iii) Women who are pregnant, lactating, of childbearing potential, or post-menopausal for < 2 years and not using a medically approved method of contraception, or who test positive on a blood-based pregnancy test
   
   iv) A documented medical history of HIV, HBV or HCV
   
   v) A documented significant cardiac, pulmonary, gastrointestinal, endocrine (other than diabetes mellitus type 1 or 2), metabolic, neurological, hepatic or nephrologic disease and/or receiving dialysis
   
   vi) Anaemia (Hb < 9 g/dL for women, or < 10 g/dL for men) or white blood cell count > 11,000/µL or platelet count < 100,000/µL or impaired renal function (creatinine > 3 mg/dL) or liver function tests > 3 times upper normal laboratory values or any indication of malnourishment (albumin < 2.8 g/dL) or any other clinically significant biochemistry, haematology and urinalysis tests
   
   vii) Any clinically significant illness during the 4 weeks preceding the screening period
   
   viii) Current or previous (within last 5 years) malignancy, other than basal cell carcinoma, or is treated by radio/chemotherapy
   
   ix) Any signs of clinical infection in the wound (which could be linked to raised body temperature, abscess, osteomyelitis, nectosis or erythema)
   
   x) Received any antibiotic treatment during the screening period
   
   xi) Evidence of infection or osteomyelitis on a plain foot X-ray at screening
   
   xii) Bed-ridden or unable to come to the clinic
   
   xiii) > 1 target non-healing diabetic foot ulcer per subject
   
   xiv) Plantar neuropathic diabetic foot ulcer is located on an active Charcot foot
   
   xv) Hind foot ulcer or foot deformity/condition that prevents the use of offloading footwear
   
   xvi) Revascularisation leg surgery within the last 6 months, or a candidate for revascularisation surgery
during the course of the study
  xvii) Glucocorticosteroid treatment (prednisone > 10 mg/day or equivalent)
  xviii) Inability to stop alternative wound healing treatment (e.g. becaplermin or other topical products) following debridement

| Participants | 1. Enrolled: 350  
2. Inclusion criteria  
   i) Type 1 or 2 diabetes mellitus  
   ii) HbA1c ≤ 12%  
   iii) Diabetic foot ulcer located below the ankle and/or on the bottom of the foot that has been present for 30 days and is of sufficient size to qualify for the study  
   iv) Good vascular perfusion of the affected limb  
3. Exclusion criteria  
   i) Gangrene, infection, or osteomyelitis  
   ii) Sensitivity to bovine collagen or chondroitin, or both  
   iii) Ulcers resulting from other health conditions besides diabetes  
   iv) Conditions or laboratory values that are not within the specified ranges |
| Interventions | 1. Intervention: dermal replacement device. Application in diabetic foot ulcer  
2. Control: moist wound therapy  
3. Co-intervention: saline plus secondary dressing and conventional wound therapy |
| Outcomes | 1. Primary outcome measure: incidence of complete wound closure: time-frame = 16 weeks; not designated as a safety issue  
2. Secondary outcome measures  
   i) Time to complete wound closure: time-frame = 28 weeks; not designated as a safety issue  
   ii) Incidence of recurrence: time-frame = 28 weeks; not designated as a safety issue  
   iii) Incidence of adverse events: time-frame = 28 weeks; designated as a safety issue |

### NCT01098357

<table>
<thead>
<tr>
<th>Trial name or title</th>
<th>A phase I/II, multicentre, randomised, controlled, and open-label trial comparing the efficacy and safety of three dose regimens of BioChaperone PDGF-BB to becaplermin gel for the treatment of diabetic foot ulcer</th>
</tr>
</thead>
</table>
| Methods             | 1. Allocation: randomised  
2. Endpoint classification: safety/efficacy study  
3. Intervention model: parallel assignment  
4. Masking: open label  
5. Primary purpose: treatment  
6. Country: India |
| Participants        | 1. Enrolled 192  
2. Inclusion criteria  
   i) Aged ≥ 18 years, with type 1 or 2 diabetes mellitus  
   ii) Single full-thickness plantar ulcer of the extremity (below the malleolus) extending through the epidermis and dermis, but not involving bone, tendons, ligaments or muscles (grade IA as defined by University of Texas Diabetic Wound Classification)  
   iii) Chronic ulcer of at least 6 weeks duration despite appropriate wound care  
   iv) Ulcer area (greatest length by greatest width), following sharp debridement, of 1-10 cm²  
   v) Well-controlled infection or cellulitis (systemic antibiotic therapy)  
   vi) Peripheral neuropathy assessed by Semmes-Weinstein monofilament test or by bioesthesimeter (vibration perception threshold)  
   vii) Adequate arterial blood supply measured by (colour) doppler ultrasonography, ABPI > 0.60, or ankle systolic pressure > 70 mmHg, or toe pressure > 30 mmHg. ABPI should be < 1.3 (which is frequently related to medial artery calcification)  
   viii) Women required to be surgically sterile, post-menopausal, or be non-nursing and agree to practice adequate contraception and have a negative pregnancy test at screening  
   ix) Provide signed informed consent before any study procedure  
3. Exclusion criteria  
   i) Ulcer of non-diabetic cause or origin, e.g. electrical, chemical or radiation insult, bedsores, vascular ulcer or Charcot deformity ulcers  
   ii) Active ulcer infection assessed by clinical examination and radiographically, if necessary. Presence of necrosis, purulence or sinus tracts that cannot be removed by debridement  
   iii) Active osteomyelitis affecting the area of the target ulcer  
   iv) Poorly-controlled diabetes (uncontrolled glycaemia: HbA1c ≥ 12%), renal failure (serum creatinine > 3.0 mg/dL), poor nutritional status (albumin < 3.0 g/dL or total protein < 6.5 g/dL)  
   v) Known connective tissue or malignant disease  
   vi) Concomitant treatment with corticosteroids, immunosuppressive agents, radiation therapy, or anticancer chemotherapy  
   vii) Use of investigational drug/device within 30 days  
   viii) Topical application of any advance wound care on this wound (growth factor, antiseptics, antibiotics or debriders) within 7 days  
   ix) Vascular reconstruction within 8 weeks. |
x) Expected noncompliance with the protocol (i.e. not available for the duration of the trial, or noncompliant with treatment or wound care), or felt to be unsuitable by the Investigator for any other reason

Interventions

After the screening visit, the eligible participant population randomly receive 1 of the following:

1. Intervention 1: BioChaperone™ PDGF-BB 25 µg/cm² applied as a spray every 2 days for 20 weeks
2. Intervention 2: BioChaperone™ PDGF-BB 12.5 µg/cm² applied as a spray every 2 days for 20 weeks
3. Intervention 3: BioChaperone™ PDGF-BB 4 µg/cm² applied as a spray every 2 days for 20 weeks
4. Intervention 4: beclapermin (Regranex) gel 6.25 µg/cm² applied daily for 20 weeks

Experimental BioChaperone PDGF-BB is a new formulation of the B isoform dimer of recombinant human platelet-derived growth factor (rhPDGF-BB) containing the new excipient Biochaperone, a dextran modified polymer. The finished product is administered as a sterile spray

Regranex: active comparator becaplermin gel (Regranex® Gel 0.01%, Systagenix, formerly and Johnson & Johnson) is a topical gel of rhPDGF-BB contained in a gel tube

All 4 groups to be assessed weekly till the 8th week (visit 10); then once every 2 weeks (14 day duration) thereafter till the end of study. The maximum number of visits expected is 16. The study data will be presented at the end of 20 weeks

Outcomes

1. Primary outcome measures:
   i) Incidence of complete wound closure: time-frame = 20 weeks; not designated as a safety issue
   ii) Incidence of complete wound closure

2. Secondary outcome measures
   i) Time to achieve complete wound closure: time-frame = 20 weeks (duration of study); not designated as a safety issue
   ii) Time to achieve complete wound closure
   iii) Percentage reduction in total ulcer surface area at each visit: time-frame = 20 weeks (study duration); not designated as a safety issue
   iv) Incidence of complete wound healing at week 10: time-frame = 10 weeks; not designated as a safety issue
   v) Safety measures: time-frame = 20 weeks (duration of study); designated as a safety issue
      a) Treatment-related adverse events with investigator’s assessment of seriousness, severity, duration and relationship to study medication
      b) Wound-related infections
      c) Changes in standard laboratory tests (haematology, biochemistry and detection of antibodies)

Starting date

June 2010 (date of first enrolment)

### APPENDICES

**Appendix 1. Glossary of medical and epidemiological terms**

<table>
<thead>
<tr>
<th>Terms</th>
<th>Definition</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ankle Brachial Index</td>
<td>Comparison of the blood pressure between the brachial artery and the posterior tibial artery. It is a predictor of peripheral arterial disease</td>
<td><a href="http://www.ncbi.nlm.nih.gov/mesh">http://www.ncbi.nlm.nih.gov/mesh</a></td>
</tr>
<tr>
<td>Term</td>
<td>Description</td>
<td>Source</td>
</tr>
<tr>
<td>-----------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Actovegin</td>
<td>A biological drug - a calf blood haemodialysate - manufactured from a natural source</td>
<td>Buchmayer 2011</td>
</tr>
<tr>
<td>Amputation</td>
<td>The removal of a limb or other appendage or outgrowth of the body</td>
<td><a href="http://www.ncbi.nlm.nih.gov/mesh">http://www.ncbi.nlm.nih.gov/mesh</a></td>
</tr>
<tr>
<td>Arginine-glycine-aspartic acid (RGD) peptide matrix (Argidine Gel®, formerly Telio-Derm Gel®, Telios Pharmaceuticals, San Diego, CA, USA)</td>
<td>This peptide matrix contains the arginine-glycine-aspartic acid amino acid sequence, through which cells in vivo become attached to macromolecules of extracellular matrix via surface integrin receptors. The matrix (intervention) is a sterile non-preserved clear viscous gel, formulated in phosphate-buffered saline and dispensed from a single-use syringe. The functional ingredient of RGD peptide matrix is a complex formed by the combination of a synthetic 18-amino acid peptide and sodium hyaluronate. It also contains added unconjugated sodium hyaluronate as a viscosity-increasing agent, and, therefore, does not need to be prepared from patient’s samples</td>
<td>O’Meara 2000</td>
</tr>
<tr>
<td>Attrition bias</td>
<td>A type of selection bias due to systematic differences between the study groups in the quantitative and qualitative characteristics of the process of loss of their members during study conduct, i.e., due to attrition among subjects in the study</td>
<td>Porta 2008</td>
</tr>
<tr>
<td>Autologous platelet gel</td>
<td>See ‘platelet-rich plasma’</td>
<td>Lacci 2010</td>
</tr>
<tr>
<td>Basic fibroblast growth factor (bFGF) (Farmitalia Carlo Erba, Milan, Italy)</td>
<td>A heparin-building, single-chain peptide of 146 amino acids, ubiquitously distributed in mesoderm- and neuroectoderm-derived tissues. This is a potent mitogen for all cell types involved in the healing process. It is highly angiogenic and chemotactic for fibroblasts and endothelial cells. bFGF is produced by recombinant DNA technology using Escherichia coli type b</td>
<td>O’Meara 2000</td>
</tr>
<tr>
<td>Bias in the presentation of data</td>
<td>Error due to irregularities produced by digit preference, incomplete data, poor techniques of measurement, technically poor laboratory procedures, or an intentional attempt to mislead</td>
<td>Porta 2008</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
<td>Reference</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------</td>
</tr>
<tr>
<td>Burning sensation</td>
<td>An abnormal feeling of burning in the absence of heat</td>
<td><a href="http://www.healthline.com/hlc/burning-sensation">http://www.healthline.com/hlc/burning-sensation</a></td>
</tr>
<tr>
<td>Callus</td>
<td>A hard, thickened area of skin occurring in parts of the body that are subjected to pressure or friction, particularly the soles of the feet and the palms of the hands</td>
<td>O’Meara 2000</td>
</tr>
<tr>
<td>Cellulitis</td>
<td>An acute, diffuse, and suppurative inflammation of loose connective tissue, particularly the deep subcutaneous tissues, and sometimes muscle, most commonly seen as a result of infection of a wound, ulcer, or other skin lesion</td>
<td><a href="http://www.ncbi.nlm.nih.gov/mesh">http://www.ncbi.nlm.nih.gov/mesh</a></td>
</tr>
<tr>
<td>Co-intervention</td>
<td>In a randomised controlled trial, the application of additional diagnostic or therapeutic procedures to members of either, some or all of the experimental and control groups</td>
<td>Porta 2008</td>
</tr>
<tr>
<td>Connective tissue disease</td>
<td>A heterogeneous group of disorders, some hereditary, others acquired, characterised by abnormal structure or function of one or more of the elements of connective tissue, i.e. collagen, elastin, or the mucopolysaccharides</td>
<td><a href="http://www.ncbi.nlm.nih.gov/mesh">http://www.ncbi.nlm.nih.gov/mesh</a></td>
</tr>
<tr>
<td>CT-102 activated platelet supernatant</td>
<td>A combination of growth factors released from ρ-granules of human platelets by thrombin</td>
<td>O’Meara 2000</td>
</tr>
<tr>
<td>(APST)</td>
<td>(Curative Technologies, Setauket, NY, USA) (synonym: platelet-derived wound-healing formula (PDWHF))</td>
<td></td>
</tr>
<tr>
<td>Debridement</td>
<td>The removal of foreign material and dead or contaminated tissue from, or adjacent to, a wound until the surrounding healthy tissue is exposed</td>
<td>O’Meara 2000</td>
</tr>
<tr>
<td>Design bias</td>
<td>The difference between a true value and that obtained through the faulty design of a study. Examples include uncontrolled studies where the effects of two or more processes cannot be separated because of lack of measurement of key causes of the exposure or outcome (confounding); also studies performed on poorly-defined populations or with unsuitable control groups</td>
<td>Porta 2008</td>
</tr>
<tr>
<td>Condition</td>
<td>Description</td>
<td>Reference</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------</td>
</tr>
<tr>
<td>Diabetes Mellitus, type 1</td>
<td>A subtype of diabetes mellitus that is characterized by insulin deficiency. It is manifested by the sudden onset of severe hyperglycemia, rapid progression to diabetic ketoacidosis, and death unless treated with insulin. The disease may occur at any age, but is most common in childhood or adolescence.</td>
<td><a href="http://www.ncbi.nlm.nih.gov/mesh">http://www.ncbi.nlm.nih.gov/mesh</a></td>
</tr>
<tr>
<td>Diabetes Mellitus, type 2</td>
<td>A subclass of diabetes mellitus that is not insulin-responsive or dependent (NIDDM). It is characterized initially by insulin resistance and hyperinsulinemia; and eventually by glucose intolerance; hyperglycemia; and overt diabetes. Type II diabetes mellitus is no longer considered a disease exclusively found in adults. Patients seldom develop ketosis but often exhibit obesity.</td>
<td><a href="http://www.ncbi.nlm.nih.gov/mesh">http://www.ncbi.nlm.nih.gov/mesh</a></td>
</tr>
<tr>
<td>Diabetic coma</td>
<td>A state of unconsciousness that is a complication of diabetes mellitus. It occurs in cases of extreme hyperglycaemia or hypoglycaemia that may occur as a complication of insulin therapy.</td>
<td><a href="http://www.ncbi.nlm.nih.gov/mesh">http://www.ncbi.nlm.nih.gov/mesh</a></td>
</tr>
<tr>
<td>Diabetic ketoacidosis</td>
<td>A life-threatening complication of diabetes mellitus (primarily of type 1) exacerbated by severe insulin deficiency and extreme hyperglycaemia. It is characterised by the metabolism of fatty acids (ketosis); dehydration; and depressed consciousness leading to coma.</td>
<td><a href="http://www.ncbi.nlm.nih.gov/mesh">http://www.ncbi.nlm.nih.gov/mesh</a></td>
</tr>
<tr>
<td>Epidermal growth factor (EGF)</td>
<td>This growth factor stimulates keratinocyte proliferation and locomotion, and inhibits fibroblast proliferation. It is a chemoattractant for mesodermal and epidermal cells.</td>
<td>O’Meara 2000</td>
</tr>
<tr>
<td>Gangrene</td>
<td>The death and decay of part of the body due to a deficiency in, or the cessation of, the blood supply. Causes can include disease, injury, atheroma in major blood vessels, frostbite and severe burns. Dry gangrene is the death and withering of tissues caused by the cessation of the local blood circulation; moist gangrene is the death and putrefactive decay of tissue due to bacterial infection.</td>
<td>O’Meara 2000</td>
</tr>
<tr>
<td><strong>Growth factors</strong></td>
<td>A group of multifunctional peptides thought to promote cellular proliferation, migration and protein synthesis. They may be derived from platelets, endothelial cells, monocytes, tissue macrophages, fibroblasts or epidermal cells</td>
<td>O’Meara 2000</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>Hypersensitivity</strong></td>
<td>Heightened reactivity to an antigen, which can result in pathologic reactions to subsequent exposure to that particular antigen</td>
<td><a href="http://www.ncbi.nlm.nih.gov/mesh">http://www.ncbi.nlm.nih.gov/mesh</a></td>
</tr>
<tr>
<td><strong>Hypotension</strong></td>
<td>Abnormally low blood pressure that can cause inadequate blood flow to the brain and other vital organs. A common symptom is dizziness, but greater negative impacts occur when there is prolonged deprivation of oxygen and nutrients</td>
<td><a href="http://www.ncbi.nlm.nih.gov/mesh">http://www.ncbi.nlm.nih.gov/mesh</a></td>
</tr>
<tr>
<td><strong>Information bias</strong></td>
<td>A flaw in measuring exposure, covariate, or outcome variables that results in different quality (accuracy) of information between comparison groups. The information bias may not be independent of selection biases. Bias in an estimate arising from measurement errors</td>
<td>Porta 2008</td>
</tr>
</tbody>
</table>
| **International Association Enterostomal Therapy classification for assessing the stage of ulcers** | **Stage I**  
An observable pressure-related alteration of intact skin, which, when compared to adjacent skin or an opposite area on the body, may include changes in one or more of the following: skin temperature (warmth or coolness), tissue consistency (firm or boggy feel), and/or sensation (pain, itching). In lightly-pigmented skin, an ulcer appears as a defined area of persistent redness, while in darker skin, an ulcer may appear with persistent red, blue or purple hues  
**Stage II**  
Partial-thickness skin loss involving epidermis or dermis, or both. The ulcer is superficial and presents as an abrasion, blister, or shallow crater  
**Stage III**  
Full-thickness skin loss involving damage to or necrosis of subcutaneous tissue that may extend down to, but not through, underlying fascia. The ulcer presents clinically | http://www.wocn.org/pdfs/WOCN_Library/Position_Statements/staging.pdf |
<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ischaemia</td>
<td>A deficiency of blood in a body part due to functional constriction, or actual obstruction, of a blood vessel</td>
<td>O'Meara 2000</td>
</tr>
<tr>
<td>Impaired glucose tolerance</td>
<td>A pathological state in which the blood glucose level is less than approximately 140 mg/100 ml of plasma at fasting, and above approximately 200 mg/100 ml plasma at 30-, 60-, or 90-minutes during a glucose tolerance test. This condition is seen frequently in diabetes mellitus, but also occurs with other diseases and malnutrition</td>
<td><a href="http://www.ncbi.nlm.nih.gov/mesh">http://www.ncbi.nlm.nih.gov/mesh</a></td>
</tr>
<tr>
<td>Neuropathic ulcer</td>
<td>An ulcer that usually occurs on the plantar surface of the foot. These ulcers are often associated with sensory neuropathy and, therefore, are often painless. They are typically surrounded by callus tissue, as they occur at sites of high mechanical pressure</td>
<td>O'Meara 2000</td>
</tr>
<tr>
<td>Oedematous (oedema)</td>
<td>Abnormal fluid accumulation in tissues or body cavities. Most cases of oedema are present under the skin in subcutaneous tissue</td>
<td><a href="http://www.ncbi.nlm.nih.gov/mesh">http://www.ncbi.nlm.nih.gov/mesh</a></td>
</tr>
<tr>
<td>Peripheral vascular disease</td>
<td>A general or unspecified disease of the blood vessels outside the heart</td>
<td>O'Meara 2000</td>
</tr>
<tr>
<td>Platelet-derived growth factors</td>
<td>Mitogenic peptide growth hormone carried in the alpha-granules of platelets released when platelets adhere to traumatised tissues. Connective tissue cells near the traumatised region respond by initiating the process of replication</td>
<td><a href="http://www.ncbi.nlm.nih.gov/mesh">http://www.ncbi.nlm.nih.gov/mesh</a></td>

6. depth | no symptoms or signs of PAD in the affected foot, in combination with palpable dorsal pedal and posterior tibial artery, or  
1. ankle-brachial index 0.9-1.10, or  
2. toe-brachial index > 0.6, or  
3. TcPO2 > 60 mmHg | symptoms or signs of PAD, but not of CLI |
| PEDIS system | 1. perfusion  
2. extent/size  
3. depth/tissue loss  
4. infection  
5. sensation | Ulcer site: forefoot (distal to tarso-metatarsal joint = 0; mid-foot/hindfoot = 1)  
Ischaemia: blood flow relatively intact (at least one pulse palpable on the affected foot = 0; evidence of ischaemia i.e. neither pulse palpable with signs of reduced tissue perfusion with, or without, gangrene = 1)  
Neuropathy: absent = 0; present = 1 (based on a routine examination using either Neurotips or 10 g nylon monofilaments) | | | | |

**Abbreviations**

NIDDM = non insulin-dependent diabetes mellitus  
UK = United Kingdom  
USA = United States of America  
VPT = vibration perception threshold
Stage D: ischaemic infected wounds

**Bacterial infection:** absent = 0; present = 1

**Area:** < 1 cm\(^2\) = 0; ≥ 1 cm\(^2\) = 1

**Depth:** superficial = 0; deep (tendon, periosteum, joint capsule, or bone) = 1

1. presence of intermittent claudication (in case of claudication, additional non-invasive assessment should be performed), as defined in the document of the International Consensus on the Diabetic Foot, or
2. ankle-brachial index < 0.9, but with ankle pressure > 50 mmHg, or
3. toe-brachial index < 0.6, but systolic toe blood pressure > 30 mmHg, or
4. TcPO\(_2\) 30-60 mmHg, or
5. other abnormalities on non-invasive testing, compatible with PAD (but not with CLI)

**GRADE 3**

CLI, as defined by:
1. systolic ankle blood pressure < 50 mmHg, or
2. systolic toe blood pressure < 30 mmHg, or
3. TcPO\(_2\) < 30 mmHg

---

**Abbreviations**

CLI = critical limb ischaemia
PAD = peripheral arterial disease
TcPO\(_2\) = transcutaneous oxygen pressure

---

Appendix 6. Assessment of risk of bias in included studies

**Generation of allocation sequence (checking for possible selection bias)**

1. Low risk (any truly random process, e.g. random number table, computer random number generator, that is likely to produce comparable groups).
2. High risk (any non-random process, e.g. odd or even date of birth, hospital or clinic record number, that is unlikely to produce comparable groups).
3. Unclear risk, if the trial was described as randomised, but the method used for the allocation sequence generation was not described.
Allocation concealment (checking for possible selection bias)

1. Low risk (e.g. telephone or central randomisation or consecutively-numbered, scaled, opaque envelopes; allocation is unlikely to be foreseen in advance or become known later).
2. High risk (open random allocation or unsealed or non-opaque envelopes, alternation, date of birth; allocation could be foreseen in advance or become known later).
3. Unclear risk, if the trial was described as randomised, but the method used to conceal the allocation was not described.

Blinding or masking (checking for possible performance and detection bias)

We assessed the adequacy of blinding separately for participants, carers/personnel and outcome assessors, and also for different outcomes or classes of outcomes.

1. Low risk: participants, carers/personnel and/or outcome assessors blinded regarding the intervention participants received, or lack of blinding could not have affected the results.
2. High risk: participants, carers/personnel and/or outcome assessors were not blinded regarding the intervention participants received and this could have affected the results.
3. Unclear risk: blinding of participants, carers/personnel and outcome assessors was not reported.

Incomplete outcome data (checking for possible attrition bias through withdrawals, dropouts, protocol deviations)

1. Low risk (any one of the following):
   i) no missing outcome data;
   ii) reasons for missing outcome data were unlikely to be related to true outcome (for survival data, censoring unlikely to be introducing bias);
   iii) missing outcome data were balanced in numbers across intervention groups, with similar reasons for missing data across groups;
   iv) for dichotomous outcome data, the proportion of missing outcomes compared with observed event risk was not enough to have a clinically relevant impact on the intervention effect estimate;
   v) for continuous outcome data, plausible effect size (difference in means or standardised difference in means) among missing outcomes was not enough to have a clinically relevant impact on observed effect size;
   vi) missing data have been imputed using appropriate methods.
2. High risk (any one of the following):
   i) reason for missing outcome data likely to be related to true outcome, with either imbalance in numbers or reasons for missing data across intervention groups;
   ii) for dichotomous outcome data, the proportion of missing outcomes compared with observed event risk enough to induce clinically relevant bias in intervention effect estimate;
   iii) for continuous outcome data, plausible effect size (difference in means or standardised difference in means) among missing outcomes enough to induce clinically relevant bias in observed effect size;
   iv) ‘as-treated’ analysis done with substantial departure of the intervention received from that assigned at randomisation; potentially inappropriate application of simple imputation.
3. Unclear risk (either of the following):
   i) insufficient reporting of attrition/exclusions to permit a judgement of ‘low risk’ or ‘high risk’ to be made (e.g. number randomised not stated, no reasons for missing data provided);
   ii) the study did not address this outcome.

Selective outcome reporting bias

1. Low risk (either of the following):
   i) the study protocol is available and all the pre-specified (primary and secondary) outcomes were reported in the final report;
   ii) the study protocol was not available but it was clear that the published reports included all expected outcomes.
2. High risk (any one of the following):
   i) not all of the study’s pre-specified primary outcomes have been reported;
   ii) one or more primary outcomes is reported using measurements, analysis methods or subsets of the data (e.g. sub scales) that were not pre-specified;
iii) one or more reported primary outcomes were not pre-specified (unless clear justification for their reporting is provided, such as an unexpected adverse effect);
   iv) one or more outcomes of interest in the review are reported incompletely so that they cannot be entered in a meta-analysis;
   v) the study report fails to include results for a key outcome that would be expected to have been reported for such a study.

3. Unclear risk: insufficient information available to permit a judgement of ‘low risk’ or ‘high risk’ to be made.

Other biases
We described for each included study any important concerns we had about other possible sources of bias (academic bias, bias in presentation data, etc.)
1. Low risk of bias, the trial appears to be free of other components that could put it at risk of bias.
2. Unclear risk, the trial may or may not be free of other components that could put it at risk of bias.
3. High risk of bias, there are other factors in the trial that could put it at risk of bias.

**Contributions of Authors**

Arturo J Martí-Carvajal: conceived, designed and coordinated the review; extracted data; checked the quality of data extraction; undertook quality assessment; analysed and interpreted data; checked quality assessment; performed part of data analysis and interpretation; performed statistical analysis; checked the quality of the statistical analysis; completed the first draft of the review; performed part of writing and editing the review; made an intellectual contribution to the review; approved the final review prior to submission; advised on the review; secured funding; wrote to study author/experts/companies; provided data and is a guarantor of the review.

Christian Gluud: checked the quality of data extraction; undertook and checked quality assessment; analysed or interpreted data; performed part of data analysis and interpretation; checked the quality of the statistical analysis; performed part of writing and editing the review; made an intellectual contribution to the review; approved the final review prior to submission and advised on the review.

Susana Nicola: extracted data; checked the quality of data extraction; checked quality assessment; made an intellectual contribution to the review; approved the final review prior to submission and wrote to study author/experts/companies.
Daniel Simancas-Racines: checked the quality of data extraction; undertook and checked quality assessment; analysed or interpreted data; made an intellectual contribution to the review; and approved the final review prior to submission.

Ludovic Reveiz: checked the quality of data extraction; undertook and checked quality assessment; analysed or interpreted data; made an intellectual contribution to the review; approved the final review prior to submission and advised on the review.

Patricio Oliva: checked the quality of data extraction; undertook and checked quality assessment; analysed or interpreted data; made an intellectual contribution to the review and approved the final review prior to submission.

Jorge Cedeño-Taborda: checked the quality of data extraction; undertook and checked quality assessment; analysed or interpreted data; made an intellectual contribution to the review; approved the final review prior to submission and advised on the review.

Contributions of editorial base

Nicky Cullum: edited the protocol; advised on methodology, interpretation and protocol content. Approved the final protocol prior to submission.

Jo Dumville: edited the review, advised on methodology, interpretation and review content. Approved the final review prior to submission.

Sally Bell-Syer: co-ordinated the editorial process. Advised on methodology, interpretation and content. Edited and copy-edited the protocol and review.

Rachel Richardson: edited the review.

Ruth Foxlee: designed the search strategy and edited the search methods section.

Declarations of interest

Arturo Martí-Carvajal: was employed in 2004 by Eli Lilly to run a four-hour workshop on 'How to critically appraise clinical trials on osteoporosis and how to teach this'. He was employed in 2007 by Merck to run a four-hour workshop 'How to critically appraise clinical trials and how to teach this'. These activities are not related to his work with The Cochrane Collaboration or any Cochrane review.

Jorge A Cedeño-Taborda: was employed as Medical Director for Organon Venezolana SA from 2002 to 2007. In 2007 he was employed by Novartis de Venezuela as an outsourced medical adviser for the development of scientific material to support the marketing of Vildagliptine. None of these activities is related to the subject of this Cochrane review.

Christian Gluud: None known.

Susana Nicola: None known.

Daniel Simancas-Racines: None known.

Ludovic Reveiz: None known.

Patricio Oliva: None known.

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

Based on Consolidated Standards of Reporting Trials (CONSORT) statement, we changed the term 'safety' into 'adverse events'. The term 'safety' may be considered to imply substantive evidence of an absence of harm. The term is often misused when there is simply absence of evidence of harm (Ioannidis 2004).
